## gesture-spec-to-character *Function*

Summary      Returns the character corresponding to a Gesture Spec object.

Package      `system`

Signature     `gesture-spec-to-character gspec => char`

Arguments    `gspec`      A Gesture Spec object

Values        `char`      A Lisp character.

Description     The function `gesture-spec-to-character` returns the Lisp `character` object corresponding to the Gesture Spec object `gspec`.  
Modifier bits in `gspec` are mapped to Lisp character bits attributes where possible. `gesture-spec-accelerator-bit` is ignored.

## get-file-stat *Function*

Summary      Provides read access to the C stat structure which describes files.  
  
**Note:** not applicable on Microsoft Windows.

| Package     | <code>system</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Signature   | <code>get-file-stat filename-or-fd =&gt; file-stat (errno)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Arguments   | <p><code>filename-or-fd</code> A string denoting a file, or a file descriptor.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Values      | <p><code>file-stat</code> On success, an object representing the stat values. On failure, <code>nil</code> is returned together with a second value.</p> <p><code>errno</code> Indicates the errno value returned by the system call. This second value is returned only in the case of failure.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description | <p><code>file-stat</code> is an object representing the stat values, as would be returned by the system call <code>stat</code> (for a filename) or the system call <code>fstat</code> (for an fd).</p> <p>The values in <code>file-stat</code> are the raw data, and it is the responsibility of the user to interpret them when needed. See the UNIX manual entry for <code>stat</code> for details.</p> <p>The values can be read from <code>file-stat</code> by these readers:</p> <ul style="list-style-type: none"> <li><code>sys:file-stat-inode</code><br/>The inode of the file.</li> <li><code>sys:file-stat-device</code><br/>The id of the device where the file is.</li> <li><code>sys:file-stat-owner-id</code><br/>The user id of the owner of the file.</li> <li><code>sys:file-stat-group-id</code><br/>The group id of the file's group.</li> <li><code>sys:file-stat-size</code><br/>The size of the file in bytes.</li> </ul> |

**sys:file-stat-blocks**

The number of 512-bytes blocks used by the file.

**sys:file-stat-mode**

The protection value of the file.

**sys:file-stat-last-access**

The time of the last access to the file in seconds from 1 January 1970.

**sys:file-stat-last-change**

The time of the last change in the data of the file in seconds from 1 January 1970.

**sys:file-stat-last-modify**

The time of the last modification of the file status in seconds from 1 January 1970.

**sys:file-stat-links**

The number of hard links to the file.

**sys:file-stat-device-type**

The device type (sometimes called Rdev).

**get-folder-path***Function*

Summary      Gets the path of a special folder on a Microsoft Windows or Mac OS X machine.

Package      `system`

Signature      `get-folder-path what &key create => result`

Arguments      `what`      A keyword.

`create`      A boolean.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | A directory pathname naming the path, or <i>nil</i> .                                         |
| Description | <p>The function <code>get-folder-path</code> obtains the current value for various special folders often used by applications. It is useful because these paths may differ between versions of the operating system. <code>get-folder-path</code> is implemented only on Microsoft Windows and Mac OS X.</p> <p><i>what</i> indicates the purpose of the special folder. For instance, <code>:common-appdata</code> means the folder containing application data for all users.</p> <p>The following values of <i>what</i> are recognized on Microsoft Windows and Mac OS X:</p> <ul style="list-style-type: none"> <li><code>:appdata</code>, <code>:documents</code>, <code>:my-documents</code>, <code>:common-appdata</code>, <code>:common-documents</code> and <code>:local-appdata</code>.</li> <li><code>:documents</code> is an alias for <code>:my-documents</code>.</li> </ul> <p>The following values are recognized on Microsoft Windows only: <code>:program-files</code>, <code>:programs</code> and <code>:common-programs</code>.</p> <p>The following values are recognized on Mac OS X only:</p> <ul style="list-style-type: none"> <li><code>:my-library</code>, <code>:my-appsupport</code>, <code>:my-preferences</code>, <code>:my-caches</code>, <code>:my-logs</code>, <code>:common-library</code>, <code>:common-appsupport</code>, <code>:common-preferences</code>, <code>:common-caches</code>, <code>:common-logs</code>, <code>:system-library</code>.</li> </ul> <p>On Mac OS X, <code>:appdata</code> is an alias for <code>:my-appsupport</code>, <code>:common-appdata</code> is an alias for <code>:common-appsupport</code>, and <code>:local-appdata</code> is an alias for <code>:common-appsupport</code>.</p> <p>If the folder does not exist and <i>create</i> is true, the folder is created. The default value of <i>create</i> is <i>nil</i>.</p> <p>If the folder does exist, <i>result</i> is <i>nil</i>.</p> | <p>In LispWorks 5.0 and previous versions, <code>get-folder-path</code> returns a string.</p> |

Example      This form constructs a pathname to a file `foo.lisp` in the user's documents directory:

```
(make-pathname
 :name "foo"
 :type "lisp"
 :defaults
 (sys:get-folder-path :my-documents))
```

## **get-user-profile-directory** *Function*

Summary      Gets the root of the user's profile on a Windows NT-based system.

Package      `system`

Signature      `get-user-profile-directory => result`

Values      `result`      A directory pathname naming the path, or `nil`.

Description      The function `get-user-profile-directory` obtains the path to the current user's profile folder on a Windows NT-based system (including Windows 2000, Windows XP, Windows Vista and Windows 7). `get-user-profile-directory` is implemented only on Microsoft Windows.

`result` names the root of the profile directory.

Note that the default path for each user's profile may differ between versions of the operating system.

Compatibility note      In LispWorks 5.0 and previous versions, `get-user-profile-directory` returns a string.

Example      On Windows 7:

```
(sys:get-user-profile-directory)
=>
#P"C:/Users/dubyा/"
```

On Windows XP:

```
(sys:get-user-profile-directory)
=>
#P"C:/Documents and Settings/dubyा/"
```

On Windows 98 SE:

```
(sys:get-user-profile-directory)
=>
nil
```

## **guess-external-format** *Function*

Summary      Tries to work out the external format

Package      `system`

Signature      `guess-external-format pathname ef-spec buffer length => ef-spec`

Arguments      `pathname`      Pathname identifying location of *buffer*.

`ef-spec`      An external format spec.

`buffer`      A buffer whose contents are examined.

`length`      Length (an integer) up to which *buffer* should be examined.

Values      `ef-spec`      An external format spec.

Description      If *ef-spec* is complete, then it is returned. Otherwise `guess-external-format` calls, in turn, functions on the list `*file-encoding-detection-algorithm*`. If a complete external format spec is returned it is used, otherwise the return value

is passed to the next function. If the name of the external format spec returned by the last function on this list is `:default`, an error of type `file-encoding-resolution-error` is signalled. The caller offers a restart for trying again with respecified `external-format` and/or `element-type` arguments. Otherwise `guess-external-format` proceeds to guess the *eol-style*.

To guess the *eol-style*, functions on the list `*file-eol-style-detection-algorithm*` are called in turn. If a complete external format spec is returned it is used, otherwise the return value is passed to the next function. If the external format spec returned by the last function on this list does not contain `:eol-style`, an error of type `file-encoding-resolution-error` is signalled.

|           | <i>Macro</i>                                                                                               |
|-----------|------------------------------------------------------------------------------------------------------------|
| Summary   | Allocates the objects produced by the specified forms to the static area.<br><br>This macro is deprecated. |
| Package   | <code>system</code>                                                                                        |
| Signature | <code>in-static-area &amp;rest body =&gt; result</code>                                                    |
| Arguments | <code>body</code> The forms for which you want the garbage collector to allocate space in the static area. |
| Values    | <code>result</code> The result of executing <code>body</code> .                                            |

|             |                                                                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | Allocates the objects produced by the specified forms to the static area. Objects in the static area are not moved, though they are garbage collected when there is no longer a pointer to the object. |
| Notes       | <code>in-static-area</code> is deprecated. Use <code>make-array</code> with <code>:allocation :static</code> where possible instead.                                                                   |
| Example     | <code>(system:in-static-area (make-string 10))</code>                                                                                                                                                  |
| See also    | <code>enlarge-static</code><br><code>make-array</code><br><code>staticcp</code>                                                                                                                        |

|             | <i>Type</i>                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | A type used to generate optimal 32-bit arithmetic code.                                                                                                                                                                                                                                                                                                                                                                                     |
| Package     | <code>system</code>                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Signature   | <code>int32</code>                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description | <p>The type <code>int32</code> is used to generate optimal 32-bit arithmetic code.</p> <p>Objects of type <code>int32</code> are generated and can be manipulated using the functions in the INT32 API but the compiler can optimize such source code by eliminating the intermediate <code>int32</code> objects to produce efficient raw 32-bit code.</p> <p>See the section “Fast 32-bit arithmetic” on page 95 for more information.</p> |

**int32\***

**int32+**

**int32-**

**int32/**

*Functions*

Summary      The arithmetic operators for **int32** objects.

Package      **system**

Signatures    **int32\* x y => int32**  
**int32+ x y => int32**  
**int32- x y => int32**  
**int32/ x y => int32**

Arguments     **x**           An **int32** object or an integer of type  
**(signed-byte 32)**.

**y**           An **int32** object or an integer of type  
**(signed-byte 32)**.

Values        **int32**      An **int32** object.

Description     The function **int32\*** is the multiply operator for **int32** objects.

The function `int32+` is the add operator for `int32` objects.

The function `int32-` is the subtract operator for `int32` objects.

The function `int32/` is the divide operator for `int32` objects.

See the section “Fast 32-bit arithmetic” on page 95 for more information about the INT32 API.

+int32-0+ *Symbol Macro*

Summary Shorthand for `(sys:integer-to-int32 0)`.

## Package system

Description The symbol macro `+int32-0+` expands to `(sys:integer-to-int32 0)`.

See also [integer-to-int32](#)

`+int32-1+` *Symbol Macro*

Summary Shorthand for `(sys:integer-to-int32 1)`.

## Package system

Description The symbol macro `+int32-1+` expands to `(sys:integer-to-int32 1)`.

| Description | The function <b>int32-aref</b> is the accessor for a <b>simple-int32-vector</b> . The reader returns an <b>int32</b> object for the value at index <i>index</i> in <i>vector</i> . The writer sets the value at index <i>index</i> in <i>vector</i> to the <b>int32</b> object or integer <i>x</i> supplied.<br>See the section “Fast 32-bit arithmetic” on page 95 for more information about the INT32 API. |                                                                           |

The function `int32-lognot` is the bitwise logical operator for `int32` objects which returns the complement of its argument `x`.

The function `int32-logorc1` is the bitwise logical operator for `int32` objects which 'inclusive ors' the complement of `x` with `y`.

The function `int32-logorc2` is the bitwise logical operator for `int32` objects which 'inclusive ors' `x` with the complement of `y`.

The function `int32-logtest` is the bitwise test for `int32` objects which returns `t` if any of the bits designated by 1 in `x` is 1 in `y`, and returns `nil` otherwise.

The function `int32-logxor` is the bitwise logical 'exclusive or' operator for `int32` objects.

See the section "Fast 32-bit arithmetic" on page 95 for more information about the INT32 API.

`int32-plusp`

`int32-zerop`

*Functions*

Summary      The `minusp`, `plusp` and `zerop` tests for an `int32` object.

Package      `system`

Signatures      `int32-minusp x => result`  
`int32-plusp x => result`  
`int32-zerop x => result`

Arguments      `x`      An `int32` object or an integer of type  
`(signed-byte 32)`.

## integer-to-int32 *Function*

Summary The constructor for `int32` objects.

Package `system`

Signature `integer-to-int32 integer => int32`

Arguments `integer` An integer of type (`signed-byte 32`).

Values `int32` An `int32` object.

Description The function `integer-to-int32` constructs an `int32` object from an integer. An error is signalled if `integer` is not of type (`signed-byte 32`).

See the section “Fast 32-bit arithmetic” on page 95 for more information about the INT32 API.

## \*line-arguments-list\* *Variable*

Summary List of the command line arguments used when LispWorks was invoked.

Package `system`

Initial Value `nil`

Description This variable contains a list of strings. These are the arguments with which LispWorks was called, in the same order. The first element is the executable itself.

You can implement command line processing in your application by testing elements in `*line-arguments-list*`. Use a string comparison function such as `string=` to compare them.

For a description of the command line arguments processed by LispWorks, see “The Command Line” on page 310.

|-----------------------|-----------------|
| <b>load-data-file</b> | <i>Function</i> |
|-----------------------|-----------------|

Summary      Loads a fasl file created by `dump-forms-to-file` or `with-output-to-fasl-file`.

Package      `system`

Signature      `load-data-file file &rest args => result`

Arguments      `file`      A pathname designator.

`args`      Arguments passed to `load`.

Values      `result`      A generalized boolean.

Description      The function `load-data-file` loads a fasl file created by `dump-forms-to-file` or `with-output-to-fasl-file`.

`load-data-file` has the same semantics as `load`, but treats fasl files differently:

- it cannot load a fasl generated by `compile-file`.
- it allows loading of fasls generated by `dump-forms-to-file` or `with-output-to-fasl-file`, including those generated by a previous version of LispWorks.

`load-data-file` is intended to work with data files generated in a previous version of LispWorks. In particular you

can load data files generated by LispWorks 4.3, LispWorks 4.4 and LispWorks 5.0 into LispWorks 5.1.

Fasl files generated by `dump-forms-to-file` or `with-output-to-fasl-file` must only be loaded using `load-data-file`.

The pathname specified by *file* must be recognized as a fasl file, otherwise `load-data-file` will load it as a text file. LispWorks recognizes a fasl by its file type matching the value of `*binary-file-type*` or being in the value of `*binary-file-types*`.

Compatibility note The default fasl file type in LispWorks 5.0 and later differs to LispWorks 4.x on Windows and Linux, as described in `compile-file`. Therefore you may need to do something like this to ensure your LispWorks 4.x data file is recognized as a fasl file when loading it in this version of LispWorks:

```
(let ((sys:*binary-file-types*
 (cons "fsl" sys:*binary-file-types*)))
 (sys:load-data-file "C:/temp/data.fsl"))
```

Compatibility note The `fixnum` type in LispWorks 5.0 and later is larger than in LispWorks 4.x on Windows and Linux. A `bignum` dumped in a LispWorks 4.x data file will be loaded as a `fixnum` in LispWorks 5.0 and later if its value is within the `fixnum` range.

| Description | <p>The function <code>locale-file-encoding</code> consults the ANSI code page on Microsoft Windows. If the code page identifier is in <code>win32:*latin-1-code-pages*</code>, <code>locale-file-encoding</code> merges <i>ef-spec</i> with <code>:latin-1</code>. This external format writes Latin-1 on output, giving an error for any non-Latin-1 characters that are written. If the code page identifier is not in <code>win32:*latin-1-code-pages*</code> then <code>locale-file-encoding</code> merges <i>ef-spec</i> with an encoding corresponding to the current code page that gives an error for characters that cannot be encoded.</p> <p><code>locale-file-encoding</code> merges <i>ef-spec</i> with <code>:latin-1</code> on Unix.</p> |                                                                                                  |

Not all of these Gesture Spec keywords will be generated by all platforms and/or keyboards.

If *modifiers* is an integer, it represents modifier keys according to the values `gesture-spec-accelerator-bit`, `gesture-spec-control-bit`, `gesture-spec-hyper-bit`, `gesture-spec-meta-bit`, `gesture-spec-shift-bit`, and `gesture-spec-super-bit`. If *modifiers* is `nil`, then `gspec` has a wild modifiers component.

The gesture `Shift+x` could potentially be represented by the unmodified uppercase character `x`, or lowercase `x` with the `Shift` modifier. In order to ensure a consistent representation the latter form is not supported by Gesture Specs by default. That is, a `both-case-p` character may not be combined with the single modifier `shift` in the accelerator argument. This can be overridden by passing a true value for `can-shift-both-case-p`.

A `both-case-p` character is allowed with `shift` if there are other modifiers. See the below for examples.

Wild Gesture Specs can be useful when specifying an input model for a `capi:output-pane`.

#### Example

```
(sys:make-gesture-spec
 97
 (logior sys:gesture-spec-control-bit
 sys:gesture-spec-meta-bit))
```

A `both-case-p` character may not be combined with the single modifier `shift` in the accelerator argument, so code like this signals an error:

```
(sys:make-gesture-spec
 (char-code #\x)
 sys:gesture-spec-shift-bit)
```

Instead you should use:

```
(sys:make-gesture-spec (char-code #\X) 0)
```

A **both-case-p** character is allowed with **shift** if there are other modifiers:

```
(sys:make-gesture-spec
 (char-code #\x)
 (logior sys:gesture-spec-shift-bit
 sys:gesture-spec-meta-bit))
```

## make-simple-int32-vector

## Function

Summary

The constructor for **simple-int32-vector** objects.

Package

**system**

Signature

**make-simple-int32-vector** *length* &key *initial-contents* *initial-element* => *vector*

Arguments

*length* A non-negative fixnum.

*initial-contents* A sequence of integers of type (**signed-byte 32**), or **nil**.

*initial-element* An integer of type (**signed-byte 32**).

Values

*vector* A **simple-int32-vector**.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns an output stream connected to stderr.                                                                                                                                                                                                                    |
| Package     | <code>system</code>                                                                                                                                                                                                                                              |
| Signature   | <code>make-stderr-stream =&gt; stream</code>                                                                                                                                                                                                                     |
| Arguments   | None.                                                                                                                                                                                                                                                            |
| Values      | <code>stream</code> An output stream.                                                                                                                                                                                                                            |
| Description | The function <code>make-stderr-stream</code> returns an output stream connected to stderr.<br><br><code>make-stderr-stream</code> returns the same stream each time. Calling <code>close</code> on this stream has no effect (except that it forces the output). |

- Notes
1. On Microsoft Windows, if the stderr is not redirected on the command line then output to the stderr stream appears in a console.  
 The console window will be created if it does not exist. That is not desirable for typical (non-console) applications. Therefore writing to the stderr stream is probably useful only in a console application (see the `:console` keyword argument in `save-image`), or when you know that stderr is going to be redirected.
  2. Ensure your delivered Windows application calls `make-stderr-stream` at runtime rather than in the build script, because it contains the handle of Windows stderr.
  3. On Mac OS X, applications that are launched from the desktop have their stderr redirected to the "console messages".

|             | <b>Function</b>                                                                                                                                                                                                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Makes a vector that can be accessed efficiently.                                                                                                                                                                                                                                      |
| Package     | <code>system</code>                                                                                                                                                                                                                                                                   |
| Signature   | <code>make-typed-aref-vector byte-length =&gt; vector</code>                                                                                                                                                                                                                          |
| Arguments   | <code>byte-length</code> A non-negative fixnum.                                                                                                                                                                                                                                       |
| Values      | <code>vector</code> A vector.                                                                                                                                                                                                                                                         |
| Description | The function <code>make-typed-aref-vector</code> returns a vector which is suitable for efficient access at compiler optimization level safety = 0.<br><code>byte-length</code> is measured in 8-bit bytes.<br>Use <code>typed-aref</code> to access <code>vector</code> efficiently. |

Examples To make a typed vector of the type `(unsigned-byte 32)` or `single-float` with length 10:

```
(make-typed-aref-vector (* 10 4))
```

To make a typed vector of the type `double-float` with length 10:

```
(make-typed-aref-vector (* 10 8))
```

## map-environment *Function*

Summary Maps functions over the bindings in an environment.

Package `system`

Signature `map-environment env &key variable function block tag`

Arguments `env` An environment or `nil`

`variable` A function designator

`function` A function designator

`block` A function designator

`tag` A function designator

Description The function `map-environment` calls `variable` for each local variable binding in `env`, `function` for each local function binding in `env`, `block` for each block binding in `env` and `tag` for each tag binding in `env`.

`variable` is called with the following arguments: `name kind info`

`name` A symbol naming a variable

`kind` One of `:special`, `:symbol-macro` or `:lexical`, which specifies the kind of binding (see `variable-information`)

|                                                                               |                                                                                                                                |
|-------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>info</i>                                                                   | The symbol-macro expansion if <i>kind</i> is<br><code>:symbol-macro</code> and is unspecified otherwise.                       |
| <i>function</i> is called with the following arguments: <i>name kind info</i> |                                                                                                                                |
| <i>name</i>                                                                   | A symbol naming a function.                                                                                                    |
| <i>kind</i>                                                                   | One of <code>:macro</code> or <code>:function</code> , which specifies the kind of binding (see <i>function-information</i> ). |
| <i>info</i>                                                                   | The macro expansion function if <i>kind</i> is <code>:macro</code> and is unspecified otherwise.                               |
| <i>block</i> is called with the following arguments: <i>name kind info</i>    |                                                                                                                                |
| <i>name</i>                                                                   | A symbol naming a block.                                                                                                       |
| <i>kind</i>                                                                   | The keyword <code>:block</code>                                                                                                |
| <i>info</i>                                                                   | Unspecified.                                                                                                                   |
| <i>tag</i> is called with the following arguments: <i>name kind info</i>      |                                                                                                                                |
| <i>name</i>                                                                   | A symbol naming a tag.                                                                                                         |
| <i>kind</i>                                                                   | The keyword <code>:tag</code>                                                                                                  |
| <i>info</i>                                                                   | Unspecified                                                                                                                    |

| Description | <p>The function <code>marking-gc</code> garbage collects (GCs) the generation specified by <i>gen-num</i>, and all younger generations. It uses mark and sweep, rather than copy.</p> <p>Mark and sweep garbage collection uses less virtual memory during its operation, but leaves the memory fragmented, which has a detrimental effect on the performance of the system afterwards. It is therefore not used automatically by the system, except to garbage collect static objects.</p> <p><code>marking-gc</code> is useful when you want to GC a generation which contains large amount (gigabytes) of data, to make sure there are no spurious pointers from this generation to a younger generation, and you do not expect many objects in the large generation to be collected. In this scenario, a Copying GC would use virtual memory which is almost double the size of the large generation during its operation, and so would possibly cause heavy paging.</p> <p>Marking GC causes fragmentation. You can reduce the amount of fragmentation by supplying either (or both) of the arguments <i>what-to-copy</i> and <i>max-size-to-copy</i>. These specify that part of the data should be collected by copying instead. Using some copying GC rather than mark and sweep will reduce the amount of fragmentation.</p> |                                                                                                                                                                                                                      |

*what-to-copy* specifies the allocation type to copy. It can be one of the main allocation types or `:weak`, meaning copy only objects in segments of that type. *what-to-copy* can also be `:all`, meaning copy objects in all segments. If *what-to-copy* is `:default` then each call to `marking-gc` chooses one of the main allocation types or `:weak` to copy, and successive calls with `:default` cycle through these allocation types.

*max-size-to-copy* can be used to limit the amount that is copied, and thus limit the virtual memory that the operation needs. If *max-size-to-copy* is non-nil, it specifies the limit, in gigabytes, of memory that can be used for copying. If there is more than *max-size-to-copy* gigabytes of data of the type *what-to-copy*, the rest of this data is garbage collected by marking. The default value of *max-size-to-copy* is `nil`, which means there is no limit on the amount that is copied.

*fragmentation-threshold* should be a number between 0 and 10. It specifies a minimum ratio between the free area in a segment that cannot be easily used for more allocation and the allocated area in this segment. Segments that are below this threshold are not copied. The default value of *fragmentation-threshold* is 1.

| Arguments             | <code>ef-spec1</code>                                                                                                                                                         | An external format spec.                                                                                         |
|                       | <code>ef-spec2</code>                                                                                                                                                         | An external format spec.                                                                                         |
| Values                | <code>ef-spec</code>                                                                                                                                                          | The resultant external format spec created from information in <code>ef-spec1</code> and <code>ef-spec2</code> . |
| Description           | The function <code>merge-ef-specs</code> returns an external format spec constructed by adding information not supplied in <code>ef-spec1</code> from <code>ef-spec2</code> . |                                                                                                                  |

Each external format spec argument is either a symbol or a list.

If *ef-spec1* and *ef-spec2* have the same value for their name component (whether they are lists or symbols), return *ef-spec1* combined with any parameters from *ef-spec2* that are not specified in *ef-spec1*.

Otherwise, if *ef-spec1* is `:default` or a list beginning with `:default`, return *ef-spec2* with parameters modified to be a union of the parameters from *ef-spec1* and *ef-spec2*, with those from *ef-spec1* taking priority.

Otherwise, return *ef-spec1* with any `:eol-style` parameter from *ef-spec2* if *ef-spec1* does not specify `:eol-style`.

| Values      | <code>stream</code>                                                                                                                                                                                                                                         | A pipe stream.                                                                 |
| Description | On Unix/Linux/Mac OS X/FreeBSD the behavior of <code>openpipe</code> is analogous to that of <code>popen</code> in the UNIX library. It creates a pipe to/from a subprocess and returns a stream. The stream can be read from or written to as appropriate. |                                                                                |

On Microsoft Windows `open-pipe` calls `CreateProcess` and `CreatePipe` and returns a bidirectional stream.

`command` is interpreted as by `call-system-showing-output`.

`direction` is a keyword for the stream direction. The default value is `:input`. Bidirectional (I/O) pipes may be created by passing `:io`. See the example below. This argument is ignored on Microsoft Windows.

`element-type` specifies the type of the stream as with `open`. The default value is `base-char`. This argument is ignored on Microsoft Windows.

`interrupt-off`, if `t`, ensures that `Ctrl+C` (SIGINT) to the Lisp-Works image is ignored by the subprocess. This argument is not implemented on Microsoft Windows.

`shell-type` specifies the type of shell to run. On Unix-like systems the default value is `"/bin/sh"`. On Microsoft Windows the default value is `"cmd"`. Note that on Windows ME/98/95 you will need to pass `"command"`.

`use-pty` is useful on Unix-like systems if the sub-process behaves differently when running interactively and non-interactively. When `use-pty` is non-nil, the input and output of the sub-process are opened using PTY (Pseudo-pty). That means that the sub-process sees its input and output as if they come from an interactive terminal. The PTY also processes special characters such as Ctrl-C the same way that an ordinary TTY does.

`use-pty` is probably not useful on Microsoft Windows as there is no concept corresponding to the Unix behavior. If `use-pty` is non-nil then it uses the `CREATE_NEW_PROCESS_GROUP` flag when creating the child, but it is not obvious when this might be useful.

`stream` supports mixed character and binary I/O in the same way as file streams constructed by `open`.

## Examples

### Example on Unix:

```
CL-USER 1 > (setf *ls* (sys:open-pipe "ls"))
Warning: Setting unbound variable *LS*
#<SYSTEM::PIPE-STREAM "ls">

CL-USER 2 > (loop while
 (print (read-line *ls* nil nil)))

"hello"
"othello"
NIL
NIL

CL-USER 3 > (close *ls*)
T
```

The following example shows you how to use bidirectional pipes.

```
CL-USER 1 > (with-open-stream
 (s (sys:open-pipe "/bin/csh"
 :direction :io))
 (write-line "whereis ls" s)
 (force-output s)
 (read-line s))
"ls: /sbin/ls /usr/bin/ls /usr/share/man/man1.Z/ls.1"
NIL
```

### Example on Microsoft Windows

```

CL-USER 40 > (setf *ls* (sys:open-pipe "dir"))
#<WIN32::TWO-WAY-PIPE-STREAM 205F03F4>

CL-USER 41 > (loop while
 (print (read-line *ls* nil nil)))

" Volume in drive Z is lispsrc"
" Volume Serial Number is 82E3-1342"
"""
" Directory of Z:\\v42\\delivery-tests"
"""
"20/02/02 11:57a <DIR> .
"20/02/02 11:57a <DIR> ..
"14/02/02 07:04p 6,815,772 othello.exe"
"14/02/02 07:07p 6,553,628 hello.exe"
" 4 File(s) 13,369,400 bytes"
" 3,974,103,040 bytes free"
NIL
NIL

CL-USER 42 > (close *ls*)
T

```

|-----------------|----------------------------------------------------------------------------------------------------|
| Summary         | Displays a HTML page in a web browser.                                                             |
| Package         | <code>system</code>                                                                                |
| Signature       | <code>open-url <i>url</i></code>                                                                   |
| Arguments       | <code><i>url</i></code> A string.                                                                  |
| Description     | The function <code>open-url</code> displays the page at the URL <code>url</code> in a web browser. |

Supported browsers are Netscape, Firefox, Mozilla, Opera on all platforms, Microsoft Internet Explorer on Microsoft Windows and Mac OS X, plus Safari on Mac OS X.

`open-url` is defined in the "hqn-web" module.

Compatibility note If your code uses the unsupported function `hqn-web:browse` please change to use `open-url` in LispWorks 5.0 and later.

Examples `(sys:open-url "www.lispworks.com")`

## **pid-exit-status** *Function*

Summary Returns the exit status of a process executed with `run-shell-command`.

Package `system`

Signature `pid-exit-status pid &key wait name => exit-status`

Arguments `pid` A process ID.

`wait` A boolean, default value `t`.

`name` A Lisp object, default value `pid`.

Values `exit-status` An integer, or `nil`.

Description The function `pid-exit-status` returns the exit status of a process executed by `run-shell-command` with argument `save-exit-status` passed a non-nil value.

If `wait` is true then `pid-exit-status` waits until the process exits, using `name` in the wait message. If `wait` is `nil` and the process has not terminated, then `pid-exit-status` returns `nil` immediately.

Notes      **pid-exit-status** is implemented only for Unix/Linux/Mac OS X.

## **pipe-kill-process** *Function*

Summary     Tries to kill the process of a pipe stream.

Package     **system**

Signature    **pipe-kill-process** *pipe-stream* => *result*

Arguments    *pipe-stream*      A pipe stream.

Values        *result*              A boolean.

Description    The function **pipe-kill-process** tries to kill the process of a pipe stream.

*pipe-stream* must be the result of **open-pipe**. **pipe-kill-process** tries to kill the process that **open-pipe** creates.

The return value **nil** means that the process has already died. In this case the process is guaranteed to have died.

The return value **t** means that the process was still alive when **pipe-kill-process** was called, and it tried to kill it.

On Microsoft Windows, it causes the process to exit, but there may be some delay until it actually exits, so the process may still be alive at the time **pipe-kill-process** returns.

On Unix it sends SIGTERM to the process, which normally would cause it to exit, but in principle the process may handle SIGTERM and continue to run.

Notes        When **open-pipe** is called with a string, it executes it using a shell (non-Windows) or cmd (Windows), so the process that

`pipe-kill-process` will kill is the shell or cmd. When `open-pipe` is called with a list, it executes the process (first element of the list) directly, and `pipe-kill-process` kills this process (the different behavior is actually documented in `call-system`).

## pointer-from-address

## *Function*

Summary      Returns the object into which the given address is pointing.

Package      `system`

Signature      `pointer-from-address address => object`

Arguments      `address`      An integer giving the address of the object.

Values      `object`      The object pointed to by `address`.

Description      The function `pointer-from-address` returns the object into which the given integer `address` is pointing. Note that this address may not be pointing into this object after a garbage collection, unless the object is static and is still referenced by another Lisp variable or object.

| Values                        | <i>gspec</i> The Gesture Spec objec that was passed.                                                                                                                                                                                                                                                                                                                                                                                                                                             |              |                        |               |                   |                          |            |                               |            |
| Description                   | The function <code>print-pretty-gesture-spec</code> prints the key-stroke represented by the Gesture Spec object <i>gspec</i> to the stream <i>stream</i> .                                                                                                                                                                                                                                                                                                                                      |              |                        |               |                   |                          |            |                               |            |

If *force-meta-to-alt* is true, then `gesture-spec-meta-bit` is represented as `Alt` in the output; otherwise it is represented as `Meta`. *force-meta-to-alt* defaults to `nil`.

If *force-shift-for-upcase* is true and *gspec* represents uppercase input such as `A`, then the `shift` modifier is printed, indicating that `Shift` is pressed to obtain the `A` character. *force-shift-for-upcase* defaults to `t`.

If *gspec* has a wild modifiers or data component (that is, `gesture-spec-modifiers` and/or `gesture-spec-data` return `nil`) then `<wild>` appears in the output.

|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|--------------------------------------------|--------------------|-----------------------|
| Summary            | Gets or sets a registry path for use with your software.                                                                                                                                                                                                                               |                |                                            |                    |                       |
| Package            | <code>system</code>                                                                                                                                                                                                                                                                    |                |                                            |                    |                       |
| Signature          | <code>product-registry-path product =&gt; path-string</code>                                                                                                                                                                                                                           |                |                                            |                    |                       |
| Signature          | <code>(setf product-registry-path) path product =&gt; path</code>                                                                                                                                                                                                                      |                |                                            |                    |                       |
| Arguments          | <table border="0"> <tr> <td style="vertical-align: top; padding-right: 20px;"><i>product</i></td><td>A Lisp object.</td></tr> </table>                                                                                                                                                 | <i>product</i> | A Lisp object.                             |                    |                       |
| <i>product</i>     | A Lisp object.                                                                                                                                                                                                                                                                         |                |                                            |                    |                       |
| Values             | <table border="0"> <tr> <td style="vertical-align: top; padding-right: 20px;"><i>path</i></td><td>The path as a string or a list of strings.</td></tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><i>path-string</i></td><td>The path as a string.</td></tr> </table>  | <i>path</i>    | The path as a string or a list of strings. | <i>path-string</i> | The path as a string. |
| <i>path</i>        | The path as a string or a list of strings.                                                                                                                                                                                                                                             |                |                                            |                    |                       |
| <i>path-string</i> | The path as a string.                                                                                                                                                                                                                                                                  |                |                                            |                    |                       |
| Description        | <p>The function <code>product-registry-path</code> returns the registry subpath defined for the product denoted by <i>product</i>, as a string.</p> <p>The function <code>(setf product-registry-path)</code> sets the registry subpath for the product denoted by <i>product</i>.</p> |                |                                            |                    |                       |

If *path* is a string it can contain backslash \ or forward slash / as directory separators - these are translated internally to the separator appropriate for the system. Note that any backslash will need escaping (with another backslash) if you input the string value via the Lisp reader.

If *path* is a list of strings, then it is interpreted like the directory component of a pathname.

This registry subpath is used when reading and storing user preferences with `user-preference`.

Note that while *product* can be any Lisp object, values of *product* are compared by `eq`, so you should use keywords.

**Notes** To store CAPI window geometries under the registry path for your product, see the entry for `capi:top-level-interface-geometry-key`. in the *CAPI Reference Manual*.

**Example**

```
(setf (sys:product-registry-path :deep-thought)
 (list "Deep Thought" "1.0"))
```

Then, on Unix/Linux/Mac OS X systems:

```
(sys:product-registry-path :deep-thought)
=>
"Deep Thought/1.0"
```

And on Microsoft Windows:

```
(sys:product-registry-path :deep-thought)
=>
"Deep Thought\\1.0"
```

`user-preference`

## room-values *Function*

**Summary** Returns information about the state of internal storage.

|             |                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>system</code>                                                                                                                                                                 |
| Signature   | <code>room-values =&gt; result</code>                                                                                                                                               |
| Values      | <p><code>result</code> A plist<br/> <code>(:total-size size</code><br/> <code>:total-allocated allocated</code><br/> <code>:total-free free)</code></p>                             |
| Description | <code>room-values</code> returns a plist containing information about the state of internal storage. This information is the same as would be printed by ( <code>room nil</code> ). |
| Notes       | In 64-bit LispWorks you can also use <code>count-gen-num-allocation</code> and <code>gen-num-segments-fragmentation-state</code> .                                                  |
| See also    | <code>count-gen-num-allocation</code><br><code>room</code>                                                                                                                          |

## run-shell-command *Function*

|           |                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package   | <code>system</code>                                                                                                                                                                                                                                       |
| Signature | <code>run-shell-command command &amp;key input output error-output separate-streams wait if-input-does-not-exist if-output-exists if-error-output-exists show-window environment element-type save-exit-status =&gt; result</code>                        |
| Signature | <code>run-shell-command command &amp;key input output error-output separate-streams wait if-input-does-not-exist if-output-exists if-error-output-exists show-window environment element-type save-exit-status =&gt; stream, error-stream, process</code> |
| Arguments | <p><code>command</code> A string, a list of strings, a simple-vector of strings, or <code>nil</code>.</p> <p><code>input</code> <code>nil</code>, <code>:stream</code> or a file designator. Default value <code>nil</code>.</p>                          |

|             |                                                                                                                                 |                                                                                                                                                              |

|             | <i>stream</i>                                                                                                                   | A stream, or <code>nil</code> .                                                                                                                              |
|             | <i>error-stream</i>                                                                                                             | A stream, or <code>nil</code> .                                                                                                                              |
|             | <i>process</i>                                                                                                                  | A process ID.                                                                                                                                                |
| Description | The function <code>run-shell-command</code> allows Unix shell commands to be called from Lisp code with redirection of the std- |                                                                                                                                                              |

out, stdin and stderr to Lisp streams. It creates a subprocess which executes the command *command*.

The argument *command* is interpreted as by `call-system`. In the cases where a shell is run, the shell to use is determined by the environment variable SHELL, or defaults to `/bin/csh` or `/bin/sh` if that does not exist.

If *wait* is true, then `run-shell-command` executes *command* and does not return until the process has exited. In this case none of *input*, *output* or *error-output* may have the value `:stream`, and the single value *result* is the exit status of the process that ran *command*.

If *wait* is `nil` and none of *input*, *output* or *error-output* have the value `:stream` then `run-shell-command` executes *command* and returns a single value *result* which is the process ID of the process running *command*.

If *wait* is `nil` and either of *input* or *output* have the value `:stream` then `run-shell-command` executes *command* and returns three values: *stream* is a Lisp stream which acts as the stdout of the process if *output* is `:stream`, and is the stdin of the process if *input* is `:stream`. *error-stream* is determined by the argument *error-output* as described below. *process* is the process ID of the process.

If *wait* is `nil` and neither of *input* or *output* have the value `:stream` then the first return value, *stream*, is `nil`.

If *wait* is `nil` and *error-output* has the value `:stream` then `run-shell-command` executes *command* and returns three values. *stream* is determined by the arguments *input* and *output* as described above. *error-stream* is a Lisp stream which acts as the stderr of the process. *process* is the process ID of the process.

If *wait* is `nil` and *error-output* is not `:stream` then the second return value, *error-stream*, is `nil`. If *error-output* is `:output`, then stderr goes to the same place as stdout.

If *input* is a pathname or string, then `open` is called with `:if-does-not-exist` if *input*-does-not-exist. The resulting `file-stream` acts as the `stdin` of the process.

If *output* is a pathname or string, then `open` is called with `:if-exists` if *output*-exists. The resulting `file-stream` acts as the `stdout` of the process.

If *error-output* is a pathname or string, then `open` is called with `:if-exists` if *error-output*-exists. The resulting `file-stream` acts as the `stderr` of the process.

This table describes the streams created, for each combination of stream arguments:

Table 40.1 The streams created by `run-shell-command`

| Arguments                                                                                                                            | <i>stream</i>                                                                               | <i>error-stream</i>                              |

| <i>input</i> is not <code>:stream</code><br><i>output</i> is <code>:stream</code><br><i>error-output</i> is <code>:stream</code>     | An input stream connected to <code>stdout</code>                                            | An input stream connected to <code>stderr</code> |
| <i>input</i> is <code>:stream</code><br><i>output</i> is not <code>:stream</code><br><i>error-output</i> is <code>:stream</code>     | An output stream connected to <code>stdin</code>                                            | An input stream connected to <code>stderr</code> |
| <i>input</i> is not <code>:stream</code><br><i>output</i> is not <code>:stream</code><br><i>error-output</i> is <code>:stream</code> | <code>nil</code>                                                                            | An input stream connected to <code>stderr</code> |
| <i>input</i> is <code>:stream</code><br><i>output</i> is <code>:stream</code><br><i>error-output</i> is <code>:output</code>         | An I/O stream connected to <code>stdin</code> , <code>stdout</code> and <code>stderr</code> | <code>nil</code>                                 |
| <i>input</i> is not <code>:stream</code><br><i>output</i> is <code>:stream</code><br><i>error-output</i> is <code>:output</code>     | An input stream connected to <code>stdout</code> and <code>stderr</code>                    | <code>nil</code>                                 |

Table 40.1 The streams created by `run-shell-command`

| Arguments                                                                                                                                                        | <i>stream</i>                               | <i>error-stream</i> |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|---------------------|
| <i>input</i> is <code>:stream</code><br><i>output</i> is not <code>:stream</code><br><i>error-output</i> is <code>:output</code>                                 | An output stream connected to stdin         | <code>nil</code>    |
| <i>input</i> is not <code>:stream</code><br><i>output</i> is not <code>:stream</code><br><i>error-output</i> is <code>:output</code>                             | <code>nil</code>                            | <code>nil</code>    |
| <i>input</i> is <code>:stream</code><br><i>output</i> is <code>:stream</code><br><i>error-output</i> is not <code>:stream</code> OR <code>:output</code>         | An I/O stream connected to stdin and stdout | <code>nil</code>    |
| <i>input</i> is not <code>:stream</code><br><i>output</i> is <code>:stream</code><br><i>error-output</i> is not <code>:stream</code> OR <code>:output</code>     | An input stream connected to stdout         | <code>nil</code>    |
| <i>input</i> is <code>:stream</code><br><i>output</i> is not <code>:stream</code><br><i>error-output</i> is not <code>:stream</code> OR <code>:output</code>     | An output stream connected to stdin         | <code>nil</code>    |
| <i>input</i> is not <code>:stream</code><br><i>output</i> is not <code>:stream</code><br><i>error-output</i> is not <code>:stream</code> OR <code>:output</code> | <code>nil</code>                            | <code>nil</code>    |

If any of *input*, *output* or *error-output* are streams, then they must be `file-streams` or `socket-streams` capable of acting as the stdin, stdout or stderr of the process.

*environment* should be an alist of strings naming environment variables and their values. The process runs in an environment inherited from the Lisp process, augmented by *environment*.

If *save-exit-status* is true, then the system stores the exit status of the process, so that it can be recovered by calling `pid-exit-status`.

|          |                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>run-shell-command</code> is implemented only for Unix/Linux/Mac OS X.                                                                                                                                                                                                                                                                                                                         |
| Example  | <pre>(multiple-value-bind (out err pid)     (sys:run-shell-command "sh -c 'echo foo &gt;&amp;2; echo bar'"'                            :wait nil                            :output :stream                            :error-output :stream)     (with-open-stream (out out)         (with-open-stream (err err)             (values (read-line out) (read-line err)))))  =&gt; "bar", "foo"</pre> |

## **safe-locale-file-encoding** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Provides a safe encoding which corresponds to the current code page on Microsoft Windows, and the locale on Unix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Package     | <code>system</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Signature   | <code>safe-locale-file-encoding pathname ef-spec buffer length =&gt; new-ef-spec</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description | <p>The function <code>safe-locale-file-encoding</code> is similar to <code>locale-file-encoding</code> except that it always returns a safe external format. That is, the external format does not signal error on writing characters not in the encoding.</p> <p>On Microsoft Windows, <code>safe-locale-file-encoding</code> consults the ANSI code page. If the code page identifier <i>id</i> is in <code>win32:*latin-1-code-pages*</code>, it merges <i>ef-spec</i> with <code>:latin-1-safe</code>. This external format writes Latin-1 on output, using 63 (ASCII '?') to replace any non-Latin-1 characters</p> |

that are written. If the code page identifier *id* is not in `win32:*latin-1-code-pages*` then `safe-locale-file-encoding` merges *ef-spec* with an encoding corresponding to the current code page that uses the code page's replacement code for characters that cannot be encoded.

`safe-locale-file-encoding` merges *ef-spec* with `:latin-1-safe` on Unix.

## set-automatic-gc-callback *Function*

|             |                                                                                                                                      |                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| Summary     | Sets a function or functions to call after an automatic GC in 64-bit LispWorks.                                                      |                                                                              |
| Package     | <code>system</code>                                                                                                                  |                                                                              |
| Signature   | <code>set-automatic-gc-callback <i>blocking-gen-num-func</i> &amp;optional <i>other-func</i> =&gt; <i>other-func</i></code>          |                                                                              |
| Arguments   | <code><i>blocking-gen-num-func</i></code>                                                                                            | A function designator for a function of two arguments, or <code>nil</code> . |
|             | <code><i>other-func</i></code>                                                                                                       | A function designator for a function of one argument, or <code>nil</code> .  |
| Values      | <code><i>other-func</i></code>                                                                                                       | A function designator for a function of one argument, or <code>nil</code> .  |
| Description | The function <code>set-automatic-gc-callback</code> sets a function or functions to call after an automatic garbage collection (GC). |                                                                              |

If *blocking-gen-num-func* is a function designator it should take two arguments: the generation number and, if *do-gc* in the last call to `set-blocking-gen-num` was a number, the number of copied segments. It is called whenever the blocking generation is GCed automatically. If *blocking-gen-num-func* is `nil`, then this callback is switched off.

If *other-func* is a function designator it should take one argument, the generation number that was GCed. It is called whenever an automatic GC occurred and *blocking-gen-num-func* was not called, either because the blocking generation was not GCed, or because *blocking-gen-num-func* was passed as `nil`. If *other-func* is `nil` (the default) then this callback is switched off.

The calls occur after the GC has finished and there is no restriction on what they can do. If the call ends up allocating enough to trigger another automatic GC, they enter again recursively.

Notes      `set-automatic-gc-callback` is implemented only in 64-bit LispWorks. It is not relevant to the Memory Management API in 32-bit implementations.

|             | <i>do-gc</i>                | One of <code>t</code> , <code>nil</code> and <code>:mark</code> , or a real number between 0 and 10, inclusive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|             | <i>max-size-to-copy</i>     | A positive real number, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|             | <i>max-size</i>             | A synonym for <i>max-size-to-copy</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|             | <i>gc-threshold</i>         | An integer greater than 12800, or a real in the inclusive range [0 100], or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Values      | <i>old-blocking-gen-num</i> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|             |                             | An integer between 0 and 7, inclusive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | <i>do-gc</i>                | One of <code>t</code> , <code>nil</code> and <code>:mark</code> , or a real number between 0 and 10, inclusive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|             | <i>max-size-to-copy</i>     | A positive real number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|             | <i>old-gc-threshold</i>     | A number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description |                             | <p>The function <code>set-blocking-gen-num</code> sets <i>gen-num</i> as the generation that blocks. That is, no object is automatically promoted out of generation <i>gen-num</i> to a higher generation.</p> <p>If <i>do-gc</i> is non-nil, then generation <i>gen-num</i> is automatically collected when needed, as defined by <i>gc-threshold</i> (see <code>set-gen-num-gc-threshold</code>).</p> <p>The actual value of <i>do-gc</i> specifies how to GC the blocking generation when required. The possible values of <i>do-gc</i> are interpreted as follows:</p> <ul style="list-style-type: none"> <li><code>t</code> Use Copying GC.</li> <li><code>:mark</code> Use Marking GC.</li> <li>A number in the inclusive range [0, 10] Use Marking GC with copying of fragmented segments. The value specifies the <i>fragmentation-threshold</i> (the same as the argument to <code>marking-gc</code>). This is the ratio between the amount of free space that cannot be easily used and the amount of allo-</li> </ul> |

cated space inside a segment. Only segments with fragmentation higher than the threshold are copied.

The default value of *do-gc* is `t`.

*max-size-to-copy* is meaningful only if *do-gc* is a number. It specifies the maximum size in Gigabytes to try to copy. If the fragmented segments contain more data than this value, only some of them are copied in each GC.

If *gc-threshold* is non-nil, it is used to set the threshold for automatic GC using `set-gen-num-gc-threshold`.

The initial setup is as if this call has been made:

```
(sys:set-blocking-gen-num 3)
```

That is, the system will GC automatically according to the default *gc-threshold* using Copying GC.

Setting the blocking generation *gen-num* to a lower number is useful into two situations:

1. When you have an operation that allocates a significant amount of data, and almost of it goes when the operation finishes, it is useful to reduce the blocking *gen-num* during the operation. The macro `block-promotion` is a convenient way of doing that.
2. If you have a good idea of how your application behaves, it may be useful to block at a lower generation (2 or 1), and then periodically call `gc-generation` explicitly to promote long living objects to a higher generation. The advantage of doing this is that you can call `gc-generation` in places where you know there are not many short-lived objects alive.

Passing a *do-gc* value other than `t` is useful when the blocking generation can be large enough that copying it all may cause very serious paging. Passing *do-gc :mark* will stop the system from copying the blocking generation, but may cause fragmentation if a significant number of long-lived objects die

after a while, and there are not explicit calls to `gc-generation` or `marking-gc`.

`set-blocking-gen-num` returns four values: the old blocking generation number, the old value of `do-gc`, the `max-size-to-copy`, and the old value of `gc-threshold`. It can be called with `gen-num nil` to query the values without changing any of them.

|          |                                                                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>set-blocking-gen-num</code> is implemented only in 64-bit LispWorks. It is not relevant to the Memory Management API in 32-bit implementations.                                   |

| Description | The function <code>set-default-segment-size</code> sets the default initial size of a segment for a specific generation and allocation type.<br><br>The default initial size is also used as the default size for enlargement of the segment.<br><br><i>allocation-type</i> can be any of the allocation types. However, if <i>allocation-type</i> is <code>:other-big</code> or <code>:non-pointer-big</code> , this function has no effect.<br><br>If <i>size-in-mb</i> is a number, it specifies the size in megabytes. If <i>size-in-mb</i> is <code>nil</code> then <code>set-default-segment-size</code> returns the default initial segment size without altering it.<br><br>The returned value, <i>segment-size</i> , is the previous default initial segment size.<br><br>During automatic garbage collections (GCs) the system collects an ephemeral generation when any of its segments for the main allocation types is full. Thus the size of the segments defines the frequency of GCs in these generations. |           |
| Notes       | <code>set-default-segment-size</code> is implemented only in 64-bit LispWorks. It is not relevant to the Memory Management API in 32-bit implementations, where <code>enlarge-generation</code> is available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |           |

| Values      | <i>on</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A generalized boolean.                 |
| Description | <p>The function <code>set-delay-promotion</code> delays promotion for generation <i>gen-num</i>, which means that objects are promoted to the next generation in the second garbage collection (GC) that they survive in generation <i>gen-num</i>. By default, objects are promoted in the first GC.</p> <p>It is not obvious under what circumstances delayed promotion is more useful than the default behavior. If you find this function useful, please let us know at Lisp Support.</p> |                                        |
| Notes       | <p><code>set-delay-promotion</code> is implemented only in 64-bit Lisp-Works. It is not relevant to the Memory Management API in 32-bit implementations.</p>                                                                                                                                                                                                                                                                                                                                  |                                        |

|             |                                                                                                                                                                                                                                                      |                                               |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|
|             | <i>modification</i>                                                                                                                                                                                                                                  | A non-negative integer, or <code>nil</code> . |
|             | <i>access</i>                                                                                                                                                                                                                                        | A non-negative integer, or <code>nil</code> . |
| Description | The function <code>set-file-dates</code> sets the modification and access times of the file <i>file</i> for each of modification and access that is non-nil.                                                                                         |                                               |
|             | On Microsoft Windows, if <i>creation</i> is non-nil, the creation time of the file is also set. <i>creation</i> is ignored on other platforms.                                                                                                       |                                               |
|             | Each keyword argument is interpreted as a universal time representing the time to set, unless it is <code>nil</code> in which case the corresponding time for <i>file</i> is not changed. Each keyword argument has default value <code>nil</code> . |                                               |
|             | An error of type <code>file-error</code> is signalled on failure.                                                                                                                                                                                    |                                               |
| See also    | <code>open</code>                                                                                                                                                                                                                                    |                                               |

| <i>gen-num</i>   | An integer between 0 and 7, inclusive.                                                                                                                                                                                                          |                 |                |                                        |                  |                                                                                                |
| <i>threshold</i> | An integer greater than 12800, or a real in the inclusive range [0 100], or <code>nil</code> .                                                                                                                                                  |                 |                |                                        |                  |                                                                                                |
| Values           | <i>old-threshold</i> A number.                                                                                                                                                                                                                  |                 |                |                                        |                  |                                                                                                |
| Description      | The function <code>set-gen-num-gc-threshold</code> sets the threshold for additional allocation that triggers a garbage collection                                                                                                              |                 |                |                                        |                  |                                                                                                |

(GC) in generation *gen-num* when this is the blocking generation (as set by `set-blocking-gen-num`). A GC is triggered when the allocation in generation *gen-num* grows more than *threshold* over the allocation after the last GC of this generation (or a GC of a higher generation).

To set the threshold, *threshold* can be an integer greater than 12800, which is interpreted as the absolute value. Alternatively *threshold* can be a real number in the inclusive range [0 100], which is multiplied by the allocation since the previous GC to get the actual threshold to set.

The default threshold for all generations is 1. That is, for all generations *gen-num*, when generation *gen-num* is the blocking generation and allocation in it has doubled since the previous GC, generation *gen-num* is collected automatically.

`set-gen-num-gc-threshold` can be called when the generation *gen-num* is not the blocking generation, and will set the value for that *gen-num*. Such a call will not take effect until the generation *gen-num* becomes the blocking generation, as set by a call to `set-blocking-gen-num` (with `:do-gc non-nil`).

Increasing the threshold reduces the number of GC calls, but may increase the virtual memory usage.

`set-gen-num-gc-threshold` returns the old threshold for the generation *gen-num*. It can be called with *threshold nil* to return the threshold value without changing it.

Notes      `set-gen-num-gc-threshold` is implemented only in 64-bit LispWorks. It is not relevant to the Memory Management API in 32-bit implementations.

| Signature   | <code>set-maximum-memory address</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Arguments   | <code>address</code> An integer address, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description | <p><code>set-maximum-memory</code> sets or removes a limit for the maximum address that the Lisp heap can grow to. If <code>address</code> is an integer, this becomes the maximum address. If <code>address</code> is <code>nil</code>, any limit set by <code>set-maximum-memory</code> is removed.</p> <p>In 32-bit implementations on platforms other than Linux and Macintosh, by default the maximum memory is not set. LispWorks (32-bit) for Linux and LispWorks (32-bit) for Macintosh both set the maximum memory on startup. In all cases the system is constrained by the size of the physical memory.</p> <p>When the maximum memory is reached (either that set by <code>set-maximum-memory</code> or the physical memory limit) the system will become unstable. Therefore this situation should be avoided. The benefit of having the maximum memory set is that a useful error is signaled if the limit is reached.</p> <p>An application which is likely to grow to the maximum memory should test the amount of available memory using <code>memory-growth-margin</code> or <code>room-values</code> at suitable times, and take action to reclaim memory. Do not rely on handling the error signaled when the maximum memory is reached, since the system is already unstable at this point.</p> |
| Notes       | <code>set-maximum-memory</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Description | <p>The function <b>set-maximum-segment-size</b> sets the maximum segment size for a generation and allocation type in 64-bit LispWorks.</p> <p><i>allocation-type</i> can be any of the allocation types. However, if <i>allocation-type</i> is :other-big or :non-pointer-big, this function has no effect.</p> <p><i>size-in-mb</i> is the size in megabytes.</p> |                                                                                                                                                            |  |  |  |

For the non-ephemeral generations (that is, the blocking generation and above), if the system needs more memory of some allocation type in some generation, its normal operation is to enlarge one of the existing segments in this generation of this allocation type. If it does not find a segment that it can enlarge, it allocates a new segment of the same allocation type in the same generation. Therefore the maximum segment size affects the number of segments that will be used.

There is an overhead to using more segments, so normally having the largest segment size which the implementation allows (256MB) is the best. Reducing the size may be useful when using `marking-gc` with *what-to-copy* non-nil or `set-blocking-gen-num` with *do-gc* a number to prevent fragmentation in the blocking generation. In this situation, reducing the size of each segment makes it easier for the system to find segments to copy, even if the *max-size-to-copy* parameter is set to a low number to avoid using too much virtual memory.

The returned value, *max-segment-size*, is the previous maximum segment size.

If *size-in-mb* is a number, it specifies the size in megabytes. If *size-in-mb* is `nil` then `set-maximum-segment-size` returns the maximum segment size without altering it.

Notes      `set-maximum-segment-size` is implemented only in 64-bit LispWorks. It is not relevant to the Memory Management API in 32-bit implementations.

| <code>function</code> | A function designator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                   |             |                       |                        |
| Description           | <p>The function <code>set-memory-check</code> sets a memory check. <code>size</code> must be an integer. It specifies the total size in bytes of the mapped areas of Lisp at which the check is triggered. <code>function</code> is a function of no arguments. After each automatic garbage collection (GC) the system checks whether the mapped area (excluding stacks) is larger than <code>size</code>. If it is larger, <code>function</code> is called with no arguments. Inside the dynamic scope of the call, the check is disabled. There are no restrictions or special considerations on what the function <code>function</code> does. The current mapped area can be found by the <code>:total-size</code> value returned by <code>room-values</code>.</p> |                   |             |                       |                        |
| Notes                 | <code>set-memory-check</code> is implemented only in 64-bit LispWorks. It is not relevant to the Memory Management API in 32-bit implementations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                   |             |                       |                        |

| Description | <p>The function <code>set-memory-exhausted-callback</code> adds a callback that is called when memory is exhausted. That is, when the system fails to map memory.</p> <p><b>Note:</b> <code>set-memory-check</code> is a more robust way to protect against memory exhaustion problems.</p> <p>If <i>function</i> is a function designator then it should be a function with signature</p> |                                                                                    |
|             | <pre><code>function <i>gen-num</i> <i>size</i> <i>type-name</i> <i>static</i></code></pre> <p><i>function</i> is expected to report what the system was trying to allocate when it failed to map memory. Its arguments are:</p>                                                                                                                                                            |                                                                                    |
|             | <i>gen-num</i>                                                                                                                                                                                                                                                                                                                                                                             | The number of the generation in which it was trying to allocate.                   |
|             | <i>size</i>                                                                                                                                                                                                                                                                                                                                                                                | The size in bytes which it was trying to allocate.                                 |
|             | <i>type-name</i>                                                                                                                                                                                                                                                                                                                                                                           | A string naming the allocation type it was trying to allocate.                     |
|             | <i>static</i>                                                                                                                                                                                                                                                                                                                                                                              | A boolean, true if it was trying to allocate a static object, and false otherwise. |
|             | <p><i>function</i> can also have the special value <code>:reset</code>, which resets the callback list to <code>nil</code>.</p> <p><i>function</i> can also be <code>nil</code>, which means do nothing but simply return the current list of callbacks.</p>                                                                                                                               |                                                                                    |

*where* defines the position in the list that the callback *function* is placed. Its allowed values are:

**:first**      *function* is placed first in the callbacks list.

**:last**      *function* is placed last in the callbacks list.

**nil**      *function* is removed from the callbacks list.

**set-memory-exhausted-callback** always first removes *function* from the callbacks list, and then adds it according to *where*. The default value of *where* is **:first**. Functions in the list are compared with **equalp**.

**set-memory-exhausted-callback** returns the callback list.

When a callback is called, Lisp already failed to map memory. This means that you must not rely on the callback to do real work. It should therefore attempt only a minimal amount of work such as clean-ups and generating debug information. It should not try to do real work.

After all the callbacks are called, the system signals an error of type **storage-exhausted**. The condition can be accessed using the accessors described for **storage-exhausted**.

**Notes**      **set-memory-exhausted-callback** is implemented only in 64-bit LispWorks. It is not relevant to the Memory Management API in 32-bit implementations.

**See also**      **set-memory-check**  
**storage-exhausted**

## **set-signal-handler** *Function*

**Summary**      Installs or removes a handler for a Unix signal.

**Note:** applicable only on UNIX/Linux/Mac OS X.

**Package**      **system**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                  |

| Signature   | <code>set-signal-handler <i>signum handler</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                  |
| Arguments   | <i>signum</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | A Unix signal number.            |
|             | <i>handler</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | A function or <code>nil</code> . |
| Description | <p><code>set-signal-handler</code> with a function <i>handler</i> configures LispWorks such that <i>handler</i> is called when the Unix signal <i>signum</i> occurs.</p> <p>If <i>handler</i> is <code>nil</code>, any handler for <i>signum</i> is removed.</p> <p><i>handler</i> should be defined to take an <code>&amp;rest</code> argument, and ignore it. There are no restrictions on <i>handler</i> other than those applying to any asynchronous function call, and that it may be called in any thread. In particular there is no need to handle the signal immediately.</p> <p>The configuration established by <code>set-signal-handler</code> is not persistent over image saving (or application delivery), so it should be called each time the image (or application) is started.</p>        |                                  |
| Notes       | <p>The currently defined signal handlers are shown in the output of the bug report template which can generated via the <code>:bug-form</code> listener command. For example, there is a <code>SIGINT</code> handler which calls <code>break</code>. You should consult Lisp Support before overwriting existing signal handlers.</p> <p>LispWorks initially has no <code>SIGHUP</code> handler. <code>SIGHUP</code> will kill a LispWorks process which does not have a <code>SIGHUP</code> handler installed. When the LispWorks IDE starts up, a <code>SIGHUP</code> handler (which attempts to release locks in the environment) is installed. However if you need a <code>SIGHUP</code> handler in a server application, for example, you should install one using <code>set-signal-handler</code>.</p> |                                  |
| Example     | <pre>(defun my-hup-handler (&amp;rest x)   (declare (ignorable x))   (cerror "Continue"          "Got a HUP signal"))</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                  |

```
(sys:set-signal-handler 1 'my-hup-handler)
```

Note that the LispWorks IDE overwrites a `SIGHUP` handler, so you would need to reinstall it after GUI startup.

|                | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                                          |               |                        |

| Description    | <p>The function <code>set-spare-keeping-policy</code> controls the behavior of the system when a segment is emptied in 64-bit LispWorks.</p> <p>If <i>policy</i> is non-nil, then when a segment in generation <i>gen-num</i> is emptied by copying all the objects out from it, it may be kept as a spare segment to be used in the future. This increases the use of virtual memory, but reduces the number of calls to <code>mmap</code> and <code>munmap</code>. It may be useful in applications that allocate at a very high rate.</p> <p>If timing an application reveals a lot (more than 5%) of time in the "System Time", and especially if this shows up in the GC times produced by <code>extended-time</code>, it may be useful to set the policy to non-nil in generation 1, 2 and maybe in generation 3.</p> <p>The default policy is <code>nil</code> for all generations, meaning that empty segments are discarded.</p> |                |                                          |               |                        |

The returned value *old-policy* is the previous policy for the generation *gen-num*.

Notes      **set-spare-keeping-policy** is implemented only in 64-bit LispWorks. It is not relevant to the Memory Management API in 32-bit implementations.

## **set-temp-directory**

*Function*

Summary     Sets the default temp directory.

Package     **system**

Signature    **set-temp-directory** *temp-dir*

Arguments    *temp-dir*       A pathname or **nil**.

Description    The function **set-temp-directory** sets the default temp directory, that is the directory that **get-temp-directory** returns, and which is also used by **create-temp-file** and **open-temp-file**.

*temp-dir* must be either a pathname of a suitable directory, or **nil**, which means use the default. The default is what the Operating System returns for a temp directory.

Notes       **set-temp-directory** affects the global setting, that is all threads, and it is not thread-safe. If you need to call it, do that during start up. When you want to use temp files not in the default temp directory, you should call **open-temp-file** or **create-temp-file** with a suitable *directory* argument.

| Arguments                   | <i>function-and-arguments</i> A list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description                 | <p>The function <b>setup-atomic-funcall</b> sets up a funcall which will be executed atomically with respect to any other calls which were also set up by <b>setup-atomic-funcall</b>.</p> <p>The call causes the execution of the form</p> <pre>(apply (car <i>function-and-arguments</i>)        (cdr <i>function-and-arguments</i>))</pre> <p>some time after the entry to <b>setup-atomic-funcall</b>. The call may happen before <b>setup-atomic-funcall</b> returns, and it is expected that normally this is what will happen. However, it may be delayed for an indefinite period, but normally this period is short (milliseconds). The execution occurs atomically with respect to other calls that were set up by <b>setup-atomic-funcall</b>.</p> <p>The call should be short, because otherwise it will delay all the other calls. If an error occurs during the call, the atomicity is no longer guaranteed.</p> <p><b>setup-atomic-funcall</b> is useful when a process needs to atomically tell another process to do something, but does not need to wait for it to finish.</p> <p><b>setup-atomic-funcall</b> causes less congestion than using a lock, and so is more efficient for locks that may cause congestion. <b>compare-and-swap</b> and <b>atomic-exchange</b> operations will be faster.</p> |

**\*sg-default-size\*** **Variable**

**Summary** Default initial size of a stack group.

## Package system

## Initial Value In LispWorks (64-bit) for Solaris:

20000

In all other implementations:

16000

**Description** The value of the variable **\*sg-default-size\*** is the initial size of a stack group, in 32 bit words (in 32-bit implementations) or in 64 bit words (in 64-bit implementations).

**\*sg-default-size\*** can be bound around a call to a process creation function. Note that setting the global value of this variable affects the size of all system processes too, so this is not recommended.

**Example** To create a process with a stack of 32000 words:

```
(let ((sys:*sg-default-size* 32000))
 (mp:process-run-function "Larger stack" '()
 #'(lambda ()
 (print (hcl:current-stack-length)))))
```

**simple-augmented-string** *Type*

## Summary The simple augmented string type.

|             |                                                                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>system</code>                                                                                                                                                     |
| Signature   | <code>simple-augmented-string length</code>                                                                                                                             |
| Arguments   | <code>length</code> The length of the string (or *, meaning any).                                                                                                       |
| Description | This is the simple version of <code>augmented-string</code> , that is, the string itself is simple. Equivalent to:<br><br><code>(simple-vector character length)</code> |
| See also    | <code>augmented-string</code>                                                                                                                                           |

## **simple-augmented-string-p** *Function*

|             |                                                                                                                   |  |
|-------------|-------------------------------------------------------------------------------------------------------------------|--|
| Summary     | Tests if an object is a simple augmented string.                                                                  |  |
| Package     | <code>system</code>                                                                                               |  |
| Signature   | <code>simple-augmented-string-p object =&gt; bool</code>                                                          |  |
| Arguments   | <code>object</code> The object to be tested.                                                                      |  |
| Values      | <code>bool</code> <code>t</code> if <code>object</code> is a simple augmented string; <code>nil</code> otherwise. |  |
| Description | This is the predicate for simple augmented strings.                                                               |  |
| See also    | <code>simple-augmented-string</code>                                                                              |  |

## **simple-int32-vector** *Type*

|         |                                                          |
|---------|----------------------------------------------------------|
| Summary | A type for simple vectors of <code>int32</code> objects. |
| Package | <code>system</code>                                      |

|             |                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signature   | <code>simple-int32-vector</code>                                                                                                                                                                                                                                                                                                                |
| Description | <p>The type <code>simple-int32-vector</code> provides simple vectors of <code>int32</code> objects and can be used to generate optimal 32-bit arithmetic code. Create a <code>simple-int32-vector</code> by calling <code>make-simple-int32-vector</code>.</p> <p>See the section “Fast 32-bit arithmetic” on page 95 for more information.</p> |

| Summary                           | Controls behavior when stack overflow is detected.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                 |
| Package                           | <code>system</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                 |
| Initial Value                     | <code>:error</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                 |
| Description                       | <p>The variable <code>*stack-overflow-behaviour*</code> controls behavior when stack overflow is detected.</p> <p>When <code>*stack-overflow-behaviour*</code> is set to <code>:error</code>, LispWorks signals an error.</p> <p>When it is set to <code>:warn</code>, LispWorks increases the stack size automatically to accommodate the overflow, but prints a warning message to signal that this has happened.</p> <p>When it is set to <code>nil</code>, LispWorks increases stack size silently.</p> |                 |
| Notes                             | Stack overflow is only detected when code was compiled with optimize qualities <code>safety &gt;= 1</code> or <code>interruptible &gt; 0</code> (see “Compiler control” on page 88l). Code compiled with                                                                                                                                                                                                                                                                                                    |                 |

`safety = 0` and `interruptible = 0` can cause an undetected stack overflow that will crash LispWorks.

Compatibility note In LispWorks 4.4 and previous on Windows and Linux platforms, automatic stack extension is not implemented. This has been fixed in LispWorks 5.0 and later.

| Description    | This predicate can be used on an object to find out whether it is allocated in static memory.<br><br>Foreign instantiations made by Lisp — for example in a Foreign Language Interface program — are made in static memory. The Lisp representations of these alien objects are not, however. Therefore <code>staticp</code> applied to an alien returns <code>nil</code> even though the alien instance itself is really allocated in static memory. To establish this, you can check the pointer to the alien instance within its Lisp representation (a structure). |                                                                                            |

| Arguments   | <i>gen-num</i>                                                                                                                                                                                                                                                                                                                                                                                                   | An integer in the inclusive range [0,7].                 |
|             | <i>function</i>                                                                                                                                                                                                                                                                                                                                                                                                  | A designator for a function of one argument, the object. |
| Values      | <code>sweep-gen-num-objects</code> returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                    |                                                          |
| Description | <p>The function <code>sweep-gen-num-objects</code> applies <i>function</i> to all the live objects in the generation <i>gen-num</i>.</p> <p><i>function</i> should take one argument, the object. It can allocate, but if it allocates heavily the sweeping becomes unreliable. Small amounts of allocation will normally happen only in generation 0, and so will not affect sweeping of other generations.</p> |                                                          |
| Notes       | <p><code>sweep-gen-num-objects</code> is not implemented in 32-bit Lisp-Works, where you can use <code>sweep-all-objects</code> instead.</p>                                                                                                                                                                                                                                                                     |                                                          |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>typed-aref</code> allows efficient access to a typed aref vector.</p> <p><code>type</code> must evaluate to one of: <code>double-float</code>, <code>float</code>, <code>single-float</code>, <code>sys:int32</code>, <code>(unsigned-byte 32)</code>, <code>(signed-byte 32)</code>, <code>(unsigned-byte 16)</code>, <code>(signed-byte 16)</code>, <code>(unsigned-byte 8)</code> or <code>(signed-byte 8)</code>.</p> <p><code>vector</code> must be an object returned by <code>make-typed-aref-vector</code>.</p> <p><code>byte-index</code> specifies the index in 8-bit bytes from the start of the data in the vector. It must be a non-negative fixnum which is less than the <code>byte-length</code> argument passed to <code>make-typed-aref-vector</code>.</p> <p><code>typed-aref</code> and <code>(setf typed-aref)</code> will be inlined to code which is as efficient as possible when compiled with <code>(optimize (safety 0))</code> and a constant type. As usual, you need to add <code>(optimize (float 0))</code> to remove boxing for the float types.</p> |
| Notes       | <p>Efficient access to foreign arrays is also available. See <code>fli:foreign-typed-aref</code> in the <i>LispWorks Foreign Language Interface User Guide and Reference Manual</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Values      | <code>result</code> A list of <code>socket-streams</code> or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  |
| Description | <p>The function <code>wait-for-input-streams</code> waits for any of the streams in the argument <code>streams</code> to be ready for input. "Ready for input" typically means that some input is available from the stream, but can also mean that the peer closed the connection or there is an attempt to connect to the socket. Note that this function first checks the buffer for buffered streams.</p> <p>When any of the streams is ready for input, <code>wait-for-input-streams</code> returns a list of all the streams that are ready, in the same order that they appear in <code>streams</code>.</p> <p>If <code>timeout</code> is non-<code>nil</code> it must be a real number, specifying a timeout in seconds. If <code>timeout</code> seconds pass and none of the streams is ready, <code>wait-for-input-streams</code> returns <code>nil</code>.</p> <p>If <code>timeout</code> is 0, <code>wait-for-input-streams</code> returns all of the streams that are ready immediately, without waiting at all. That is, it behaves like <code>listen</code> on many streams.</p> <p>If <code>wait-function</code> is supplied, it is called periodically with no arguments, and if it returns non-<code>nil</code> then <code>wait-for-input-streams</code> returns <code>nil</code>. Note that, like the <code>wait-function</code> of <code>process-wait</code>, <code>wait-function</code> is called often and on other threads, so need to be an inexpensive call and independent of dynamic context.</p> |  |

If *wait-reason* is supplied it is used as the *wait-reason* for the Lisp process that calls `wait-for-input-streams` while it is waiting.

Notes      `wait-for-input-streams` may return the list *streams* that was passed to it as is, if all the streams are ready.

## **wait-for-input-streams-returning-first**                          *Function*

Summary     Waits for input on a list of socket streams, returning the first stream that is ready.

Package     `system`

Signature    `wait-for-input-streams-returning-first streams &key wait-function wait-reason timeout => result`

Arguments    *streams*        A list, each member of which is a `socket-stream`.

*wait-function*    A function of no arguments.

*wait-reason*     A string.

*timeout*        A real number or `nil`.

Values       *result*        A `socket-stream` or `nil`.

Description    The function `wait-for-input-streams-returning-first` behaves just like `wait-for-input-streams` except that it returns the first stream in the list *streams* that is ready for input.

| Signature   | <code>with-modification-change <i>modification-place</i> &amp;body <i>body</i></code>                                                                                                                                                                                                                                                                                                                              |
| Arguments   | <i>modification-place</i> A place as defined in Common Lisp which can receive a fixnum.<br><i>body</i> Lisp code                                                                                                                                                                                                                                                                                                   |
| Description | The macro <code>with-modification-change</code> , together with the macro <code>with-modification-check-macro</code> , provides a way for a body of code to execute and check whether there was any "modification" during this execution, where modification is execution of some other piece of code.<br><br>See "Aids for implementing modification checks" on page 193 for the full description and an example. |
| Notes       | <i>modification-place</i> does not need to be one of the places defined for low level atomic operations.                                                                                                                                                                                                                                                                                                           |
| See also    | <code>with-modification-check-macro</code>                                                                                                                                                                                                                                                                                                                                                                         |

|------------------------------------|----------------|------------------------------------------------------------------------------------|
| Summary                            |                | A debugging macro which executes code with all other threads temporarily disabled. |
| Package                            |                | <code>system</code>                                                                |
| Signature                          |                | <code>with-other-threads-disabled &amp;body body =&gt; results</code>              |
| Arguments                          | <i>body</i>    | Code.                                                                              |
| Values                             | <i>results</i> | The results of evaluating <i>body</i> .                                            |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The macro <code>with-other-threads-disabled</code> disables all the other threads (that is, the <code>mp:process</code> objects), executes <i>body</i> and then enables the other threads. Thus it guarantees "single-thread execution" for the forms in <i>body</i>.</p> <p>The point at which each of the other threads is stopped is not well-defined. It is always a GC safe point, but it can be inside manipulating some data structure or inside a lock. As a result, if the code in <i>body</i> accesses a data structure or tries to lock a lock, it may see an inconsistent structure or get an error about calling <code>process-wait</code> when scheduling not is allowed.</p> <p>As a result, <code>with-other-threads-disabled</code> is safe only if the code in <i>body</i> does not do anything that accesses trees of pointers and expects them to be in a consistent state and does not use locks. Any other code may, rarely but not never, get some unexpected error.</p> <p><code>with-other-threads-disabled</code> is useful for:</p> <ul style="list-style-type: none"><li>• the most accurate timing possible of specific operations</li><li>• running <code>sweep-all-objects</code> reliably</li><li>• "freezing" the program when something unexpected occurs and you want to debug it in the terminal.</li></ul> |
| Notes       | <p><code>with-other-threads-disabled</code> cannot be guaranteed to be 100% safe in all cases, and therefore must not be used in end-user applications. It is useful for debugging purposes.</p> <p>The LispWorks IDE relies on multithreading and will not work while the code in <i>body</i> executes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| See also    | <code>sweep-all-objects</code><br><code>time</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

# 41

## Miscellaneous WIN32 symbols

This chapter describes miscellaneous symbols available in the `WIN32` package.

The `WIN32` package also includes functions for accessing the Microsoft Windows registry API, the DDE client interface, and the DDE server interface. These are documented in separate chapters in this manual.

**Note:** the `WIN32` package is not a supported implementation of the Win32 API. You should not use symbols in the `WIN32` package unless they are documented in this manual. Instead, define your own interfaces to Windows functions as you need - see the *LispWorks Foreign Language Interface User Guide and Reference Manual* for details.

**Note:** This chapter applies only to LispWorks for Windows, and not the UNIX, Linux, x86/x64 Solaris, FreeBSD or Mac OS X platforms.

| Arguments   | <i>sid-string</i> | A string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Values      | <i>result</i>     | A string or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description |                   | The function <code>canonicalize-sid-string</code> returns the canonical format of the SID specified by <i>sid-string</i> . If the string is already canonical (in the S-1.. format) it returns a string which is equal to it. When the string is an alias, it returns the canonical form. The aliases are documented in the MSDN in the page titled "SID strings" (search for <code>SDQL_ANONYMOUS</code> ).<br><br><code>canonicalize-sid-string</code> returns <code>nil</code> for an unrecognized SID. |

|------------------------------|------------------|---------------------------------------------------------------------------------------|
| Summary                      |                  | Opens a stream connection to a named pipe.                                            |
| Package                      |                  | <code>win32</code>                                                                    |
| Signature                    |                  | <code>connect-to-named-pipe name &amp;key host errorp direction</code>                |
| Arguments                    | <i>name</i>      | A string.                                                                             |
|                              | <i>host</i>      | A string or <code>nil</code> .                                                        |
|                              | <i>errorp</i>    | A boolean.                                                                            |
|                              | <i>direction</i> | One of the keywords <code>:io</code> , <code>:input</code> and <code>:output</code> . |
| Values                       | <i>stream</i>    | A stream or <code>nil</code> .                                                        |
|                              | <i>keyword</i>   | A keyword or <code>nil</code> .                                                       |
|                              | <i>condition</i> | An error condition or <code>nil</code> .                                              |

Description     The function `connect-to-named-pipe` opens a connection to a named pipe and returns a stream connected to it that can be used like any other stream.

*name* is the pipe name. It can contain any character except #\\ (according to the MSDN). For successful connection another process must have already created a pipe with that name, with the right input/output direction and permissions for the caller of `connect-to-named-pipe`, and tried to connect to it but has not succeeded yet. In LispWorks this is done by `open-named-pipe-stream`. The Windows function is `ConnectNamedPipe`.

*host*, if non-nil, specifies a host on which the named pipe was created. `host nil` means the current machine.

*direction* specifies the direction of input/output. It needs be allowed by the pipe (in inverse, that is if `connect-to-named-pipe` gets direction `:input` then the pipe must have been opened for output, for example by calling `open-named-pipe-stream` with *direction* `:output` or `:io`). The default value of *direction* is `:io`.

*errorp* specifies what to do in case of failure. If it is non-nil (the default), an error is signaled. If it is `nil`, then `connect-to-named-pipe` returns *stream nil*, *keyword* is a descriptive keyword, and *condition* is an error condition. *keyword* can be one of:

**:does-not-exist**

There is no named pipe with this name.

**:all-in-use**

There is at least one named pipe with this name, but all are already connected.

**:access-denied**

There is already a named pipe with this name, but it denies access. That may be either because the permissions of the named

pipe do not allow the connection, or because other security features of the host system block the connection.

**:error** An unknown error.

On success `connect-to-named-pipe` returns a stream and the other two returned values are both `nil`.

## dismiss-splash-screen *Function*

Summary Makes a startup screen disappear.

Package `win32`

Signature `dismiss-splash-screen &optional forcep`

Arguments `forcep` A generalized boolean.

Description The function `dismiss-splash-screen` makes a startup screen (as specified via the `:startup-bitmap-file` delivery keyword) disappear.

If `forcep` is `nil` then the startup screen is displayed for a minimum of 5 seconds before disappearing. If `forcep` is true then the startup screen disappears when `dismiss-splash-screen` is called. The default value of `forcep` is `nil`.

If `dismiss-splash-screen` is not called, the startup screen appears for 30 seconds.

**Note:** the user can dismiss the startup screen by clicking on it.

For more information about specifying a startup screen in your application, see the entry for `:startup-bitmap-file` in the *LispWorks Delivery User Guide*.

| Signature                              | <code>impersonating-named-pipe-client (named-pipe-stream &amp;key fail-form fail-no-read-form) &amp;body body</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Arguments                              | <p><i>named-pipe-stream</i> A named pipe stream.</p> <p><i>fail-form</i> A Lisp form.</p> <p><i>fail-no-read-form</i> A Lisp form.</p> <p><i>body</i> Lisp forms.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description                            | <p>The macro <code>impersonating-named-pipe-client</code> executes the code of <i>body</i> while impersonating the client of the named pipe.</p> <p><i>named-pipe-stream</i> must be the result of <code>open-named-pipe-stream</code>.</p> <p>For the impersonation to work, some input must have already been read from the pipe. If impersonation is used on a named pipe from which nothing was read, it calls <code>error</code> unless <i>fail-no-read-form</i> is supplied, in which case it executes this form. For all other kinds of failure <i>fail-form</i> is executed.</p> <p>Apart from mechanism used to find the user to impersonate, <code>impersonating-named-pipe-client</code> behaves identically to <code>impersonating-user</code>. See <code>impersonating-user</code> for further details.</p> |
| Notes                                  | The limitation that some input must have been read is an undocumented restriction in the underlying Microsoft Windows functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Summary     | Executes code while impersonating the user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |       |
| Package     | <code>win32</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |
| Signature   | <code>impersonating-user (<i>user-name</i> <i>password</i> &amp;key <i>domain</i> <i>logon-type</i> <i>fail-form</i>) &amp;body <i>body</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |

| Description | <p>The macro <code>impersonating-user</code> executes the code of <i>body</i> while impersonating a specified user.</p> <p><i>user-name</i> and <i>password</i> specify login credentials. In general, these are strings but the symbol <code>t</code> as <i>user-name</i> is treated specially to mean the user that is currently interacting with the console of the computer (<i>password</i> is ignored in this case).</p> <p><i>domain</i>, if non-<code>nil</code>, must be a string specifying the domain or server where the account database to find the user is held. It can be <code>".</code> meaning the local database. <i>domain nil</i> means use the default domain or server, as defined by Windows.</p> <p>The <i>logon-type</i> keywords are mapped to the <code>LOGON32_LOGON_*</code> constants which are documented in the MSDN entry for <code>LogonUser</code>. The default value <code>nil</code> of <i>logon-type</i> is treated as an alias for <code>:interactive</code>.</p> |       |

*body* is evaluated only if the impersonation is successful. If the impersonation is not successful for any reason, *body* is not executed, and instead *fail-form* is evaluated.

On success, `impersonating-user` returns the result of the last form of *body*. On failure, it returns the result of *fail-form*.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <p>Impersonation means that, in operations where the user identity makes a difference, the user identity is the impersonated user rather than the user running the process. For example, when opening a file the system uses the credentials of the impersonated user to check the access control list of the file. When creating a file, the impersonated user is also used as the owner and creator of the file.</p> <p>The process that tries to impersonate must have special privilege to do that. Processes do not normally have these privileges. The processes that do are those that run with system credentials, for example services. Impersonation is used by these processes to perform specific operations with the credentials of some user rather than the system user.</p> <p>Impersonation can also be used when a service process wants to start a process to interact with the user. In that situation, the new process must run as the user. To do that, you start process inside the scope of <code>impersonating-user</code>, for example by calling <code>call-system</code> or <code>open-pipe</code>. Normally you will want to run as the user that is currently logged on the console (see the special <i>user-name</i> value <code>t</code> above).</p> |

| Summary                     | Windows Code Pages for which Latin-1 encoded files are used.                                                                                                                                                                                                                                                                                                                                                                              |
| Package                     | <code>win32</code>                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Initial Value               | <code>(1252 28591)</code>                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description                 | <p>The value of <code>*latin-1-code-pages*</code> is a list of integers, which must be Windows code page identifiers. When the current Code Page is on this list, the default file encoding detection algorithm will cause <code>(:latin-1 :encoding-error-action 63)</code> to be used for file I/O. Files will be written as Latin-1 with '?' replacing any non-Latin-1 character. This is faster than converting to the code page.</p> |

If `safe-locale-file-encoding` is used for file encoding detection, then the `:latin-1-safe` external format will be used.

|          |                                                                                                                                                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | The LispWorks editor binds <code>*latin-1-code-pages*</code> to <code>nil</code> when reading and writing files, in order to ensure that code page characters outside of Latin-1 are handled regardless of the configuration of <code>open</code> . |

|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Holds the external format corresponding to the current Windows multi-byte code page.                                                                                                                                                                                              |
| Package     | <code>win32</code>                                                                                                                                                                                                                                                                |
| Description | This variable holds the external format corresponding to the current Windows multi-byte code page. It is automatically initialized to the right value, when the image is started. If you change the code page (using <code>_setmbcp</code> ), you need to set this variable, too. |

| Description                   | The function <code>open-named-pipe-stream</code> creates a stream that communicates via a named pipe, and then tries to establish a connection. For a connection to be established, another process (which can be a Lisp process in the same image, or another process altogether) must connect to it. In LispWorks this is done by <code>connect-to-named-pipe</code> , other software                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                     |                                |                         |            |                           |                                          |                         |                                                                 |                          |                                |                      |                                     |                            |                                                   |                        |                                                                        |                               |            |                     |                                     |

does by the underlying Windows function `ConnectNamedPipe`.

`open-named-pipe-stream` returns three values. `stream` is a stream on success, and `nil` if there is an error and `errorp` is `nil`. If `open-named-pipe-stream` returns a stream and `connectedp` is non-`nil`, the stream is connected and is ready for input/output operations like a normal stream. `condition` is an error condition if an error occurred and `errorp` is `nil`, otherwise it is `nil`.

When `open-named-pipe-stream` returns a stream and `connectedp` is `nil` (which can happen when `timeout` is non-`nil` or `wait-function` returns `t`), the stream is valid but is not ready for I/O and gives an error for any reading or writing calls. In this case the function `wait-for-connection` must be used to establish the connection, and once it returns non-`nil` the stream is ready for input/output operations.

Note that that if you stop using a stream before it is connected, it still must be closed (by `cl:close`) to get rid of the named pipe.

The creation has two steps:

1. Creating the named pipe. This is controlled by `name`, `max-number`, `direction`, `access`, `inherit-access-p`, `allow-remote` and `errorp`.
2. Waiting for connection. This is controlled by `timeout`, `wait-reason`, and `wait-function`.

`name` is the pipe name. It can contain any character except `#\\` (according to the MSDN). `open-named-pipe-stream` prepends to it the pipe prefix `\.\.\pipe\`. It needs to be highly unique, because on the same machine it is visible to all processes.

`direction` specifies the direction of I/O with the conventional meaning (as in Common Lisp file streams). The default value of `direction` is `:io`. All simultaneous opened pipes with the same name on the same machine must be opened with the

same value of *direction*. If different *direction* values are used, it causes `open-named-pipe-stream` to give an error.

*max-number* specifies the maximum number of simultaneously existing pipes with the same name on the local machine. By default it is unlimited. All simultaneous pipes with the same name on the same machine must have the same *max-number*, though currently this is not enforced.

*access* specifies access permission, which controls who can connect to the pipe. If it is `nil`, the permissions of the current thread are inherited and used (*inherit-access-p* is ignored in this case), and if *access* is `:world` the pipe is created with no restrictions. Otherwise *access* has to be a keyword, a list, an integer or a string, and it is passed to `security-description-string-for-open-named-pipe`. See the entry for `security-description-string-for-open-named-pipe` for details. The result of `security-description-string-for-open-named-pipe`, potentially with the inherited access appended, is passed to the Windows function `ConvertStringSecurityDescriptorToSecurityDescriptor` to generate the descriptor that is used when creating the pipe.

*inherit-access-p* controls whether the permissions of the current thread are inherited when *access* is not `nil` or `:world` or a string. When it is not `nil`, the permissions of the current thread are appended to what is specified by *access* (which means that the specification in *access* takes precedence). The default value of *inherit-access-p* is `t`.

*allow-remote* controls whether the pipe can be connected from another machine. The default value of *allow-remote* is `nil`.

*errorp* controls what happens when there is a failure because of one of these possibilities:

1. `security-description-string-for-open-named-pipe` returns `nil` because *access* contains unknown entities (for example a user name that does not exist on the local machine)

2. Converting the string that `security-description-string-for-open-named-pipe` returned to a security descriptor failed. That can happen if `access` is a string in bad format or a list containing strings in bad format.
3. `open-named-pipe-stream` failed for some other reason, for example it reached the limit on the number of the pipes with this name, or tried to open it with a different `direction` from the previous call.

When there has been a failure, if `errorp` is non-nil an error is signalled, and if `errorp` is nil then `open-named-pipe-stream` returns `stream` nil and `connectedp` nil with the error condition returned as the third value `condition`. The default value of `errorp` is t.

Once the pipe has been successfully created, `open-named-pipe-stream` uses `wait-for-connection` to establish the connection, passing `timeout`, `wait-reason` and `wait-function`, and returns the stream as first value, the result of `wait-for-connection` as the second value, and nil as the third value. See the description of `wait-for-connection` for details.

To connect to the other side of the pipe from Lisp, use `connect-to-named-pipe`. The Microsoft Windows function is `ConnectNamedPipe`.

**security-description-string-for-open-named-pipe**

*Function*

Summary

Interprets an access specification and generates a Security Descriptor String.

|             |                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Values      | <code>result</code>      | A string or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | <code>fail-type</code>   | Undefined, or a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|             | <code>fail-item</code>   | Undefined, or a keyword, an integer, a string or a list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description |                          | <p>The function <code>security-description-string-for-open-named-pipe</code> interprets <code>access-spec</code> and generates from it a Security Descriptor String as defined by Windows. See the MSDN for documentation of "Security Descriptor String Format".</p> <p><code>security-description-string-for-open-named-pipe</code> has quite limited capabilities, and the string that it generates contains only the DACL part of the descriptor.</p> <p>If <code>access-spec</code> is a keyword, then its symbol name specifies a SID (Security Identifier). This SID gets read/write permission. The SID can be either standard representation (which looks like "<code>s-1-...</code>") or one of the aliases. The aliases are documented in the MSDN in the page titled "SID strings" (search for <code>SDDL_ANONYMOUS</code>). In general they have two letters, for example <code>:AU</code> means authenticated users. The common standard strings are documented in the MSDN page titled "Well-known SIDs" (search for <code>SECURITY_WORLD_RID</code>). For example, <code>:S-1-15-11</code> means authentication users. Any standard strings is acceptable, not only the documented ones, provided that it specifies a valid SID. For example, you can find the SID of a user by <code>user-name-to-sid-string</code>, intern it in the keyword package and use this (but it is better to pass a list (<code>:user</code>) as described below).</p> |

If *access-spec* is an integer, it must be one of the integers in the `WELL_KNOWN_SID_TYPE Enumeration` as documented in the MSDN. For example, 17 means authenticated users. The corresponding SID gets read/write permission.

If *access-spec* is a string, it is returned as-is. In this case it is the responsibility of the programmer to ensure that the string is valid. Note that if this string is used in `open-named-pipe-stream`, `open-named-pipe-stream` does not inherit the access even if *inherit-access-p* is non-nil.

If *access-spec* is a list, then each element in the list must be one of:

A string      The string must a correct ACE (Access Control Entry) string, as described in the MSDN (search for "ACE strings"). The string must contain the opening and closing brackets, and can contain more than one ACE. `security-description-string-for-open-named-pipe` does not check the syntax in the string, and if the ACE is wrong the result string would be invalid.

A keyword      This is interpreted as when *access-spec* is a keyword, and the corresponding SID gets read/write permission.

An integer      This is interpreted as when *access-spec* is an integer, and the corresponding SID gets read/write permission.

A list of the form (**keyword** *SID-spec* &rest *permissions*)

The first element *keyword* specifies how to interpret the *SID-spec*. The possible keywords are `:user`, when *SID-spec* must be a string and should name a user on the local machine, and `:sid`, when *SID-spec* must be a keyword, an integer or a string specifying the SID. Integers and keywords are inter-

pretted as above, and strings are interpreted in the same way as keywords. If *permissions* are not supplied, they default to (:read :write). When they are supplied, they are keywords specifying permission. Currently supported keywords are (i) one of :read or :disallow-read (ii) one of :write or :disallow-write, specifying the obvious meaning. It is an error if a keyword is repeated or if an incompatible pair is passed.

`security-description-string-for-open-named-pipe` returns 3 values. When successful, *result* is the string and the other return values are undefined. When it fails, which can be because it is given an unrecognized SID specifier, *result* is `nil`, *fail-type* is a short string giving the type of the item that fails, and *fail-item* is the item in the list that fails when *access-spec* is a list.

Notes

1. When the argument is syntactically incorrect, `security-description-string-for-open-named-pipe` signals an error. It fails and returns `nil` only when a SID specifier of an acceptable type does not specify a SID.
2. Except when given a string which is returned as-is, `security-description-string-for-open-named-pipe` works by generating an ACE (Access Control Entry) string for each SID giving it the read and write permission, except in the case when either :disallow-write or :disallow-read is used, when it generates an ACE string denying permission. All the ACEs are then concatenated and "`D:`" is prepended, thus generating a Security Descriptor String containing only the DACL.
3. Experimentally, you can connect to a named pipe only if you have both read and write permission, even when opening it for only read or only write. Thus when this function is used from `open-named-pipe-stream`, the keywords :disallow-read etc are not very useful. They

are useful only when you want to deny access for a specific SID, by using `:disallow-read` and `:disallow-write`.

4. The order of the items in the list is significant: earlier items override later items.
5. Disallowing permission, for example by using `:disallow-read`, is not the same as not allowing it, because in the latter case a later ACE can give the SID the permission. Disallowing prevents later ACEs from giving permission.
6. Using a string or ACE strings in the list allows the user to generate a more elaborate string than `security-description-string-for-open-named-pipe` knows how to generate. In this case the returned string may be invalid. When this happens from `open-named-pipe-stream`, `open-named-pipe-stream` will get a failure and signal or return an error according to `errorp`.

Examples Any of these gives permissions to all authenticated users:

```
:AU
 17
'(:AU)
'(17)
'((:SID :AU))
'((:SID "AU"))
'((:SID 17))
```

Also, all of the above with `AU` replaced by `s-1-5-11` will give permission to all authenticated users.

This gives permissions to all authorized users except the user "`exclude`".

```
'((:use "exclude" :DISALLOW-READ :DISALLOW-WRITE)
:AU)
```

|                               |                 |
|-------------------------------|-----------------|
| <b>set-application-themed</b> | <i>Function</i> |
|-------------------------------|-----------------|

Summary      Controls whether LispWorks should be themed.

Package      `win32`

Signature      `set-application-themed on/off`

Arguments      `on/off`      A generalized boolean.

Description      The function `set-application-themed` controls whether a LispWorks application should be themed.

On Windows XP, LispWorks is "themed", that is it uses the current theme of the desktop. You can switch this off by calling

```
(win32:set-application-themed nil)
```

On non-XP systems, or when the application does not have Common Controls 6, this call has no effect.

`set-application-themed` affects only windows that are created after it was called. Normally, it should be called before any window is created, so all LispWorks windows will appear with the same theme. However, `set-application-themed` can be called multiple times in the same run.

**str**

**lpcstr**

**lpstr**

*FLI type descriptors*

Summary      Types converting to ANSI strings.

Package      `win32`

Signature      `str &key length`  
`lpcstr &key max-length`  
`lpstr &key max-length`

Description      `str` is an ANSI string.

`lpcstr` is a reference-pass pointer to an ANSI string.

`lpstr` is a reference (in/out) pointer to an ANSI string.

These types are ANSI only. Use these if you do not need the power of Unicode on Windows XP/Vista/7. Take care to interface to ANSI functions named like `FooBarA`, with the `A` suffix.

| <i>stream</i>        | A named pipe stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |               |                      |                |                                                   |                    |                                 |                      |                                              |
| <i>timeout</i>       | A non-negative real number, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |               |                      |                |                                                   |                    |                                 |                      |                                              |
| <i>wait-reason</i>   | A string, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |               |                      |                |                                                   |                    |                                 |                      |                                              |
| <i>wait-function</i> | A function designator, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |               |                      |                |                                                   |                    |                                 |                      |                                              |
| Values               | <i>connectedp</i> A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |               |                      |                |                                                   |                    |                                 |                      |                                              |
| Description          | <p>The function <code>wait-for-connection</code> waits until it succeeds to establish a connection for the stream <i>stream</i>, or <i>timeout</i> seconds passed or <i>wait-function</i> returns non-nil, and returns a value indicating whether the connection is established successfully.</p> <p><i>stream</i> must be a stream of the right type. Currently the only supported stream is a named pipe stream (the result of <code>open-named-pipe-stream</code>).</p> <p><i>timeout</i> can be <code>nil</code> or a real number specifying the time in seconds before <code>wait-for-connection</code> returns without establishing a connection.</p> <p><i>wait-reason</i>, if non-nil, needs to be a string specifying the wait reason. It has the same semantics as the <i>wait-reason</i> argument of <code>process-wait</code>.</p> <p><i>wait-function</i>, if non-nil, must be a function of no arguments. If it returns non-nil, <code>wait-for-connection</code> returns <code>nil</code>.</p> |               |                      |                |                                                   |                    |                                 |                      |                                              |

*This chapter applies only to LispWorks for Windows*

`wait-for-connection` can be repeatedly called on the same stream. If the stream has already established a connection, it returns true immediately.

Notes      *wait-function* has the same limitations as the *wait-function* of `process-wait`.

## The Windows registry API

This chapter describes the Microsoft Windows registry API, which is available in the `WIN32` package

The `WIN32` package also includes functions for accessing miscellaneous Windows functionality, the DDE client interface, and the DDE server interface. These are documented in separate chapters in this manual.

**Note:** the `WIN32` package is not a supported implementation of the Win32 API. You should not use symbols in the `WIN32` package unless they are documented in this manual. Instead, define your own interfaces to Windows functions as you need - see the *LispWorks Foreign Language Interface User Guide and Reference Manual* for details.

**Note:** this chapter applies only to LispWorks for Windows, and not the UNIX, Linux, x86/x64 Solaris, FreeBSD or Mac OS X platforms.

## collect-registry-subkeys *Function*

|           |                                                                                                                           |                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| Summary   | Returns names of the subkeys of a registry key.                                                                           |                                             |
| Package   | <code>win32</code>                                                                                                        |                                             |
| Signature | <code>collect-registry-subkeys subkey &amp;key root max-name-size max-names errorp value-function =&gt; subsubkeys</code> |                                             |
| Arguments | <code>subkey</code>                                                                                                       | A string specifying the name of the key.    |
|           | <code>root</code>                                                                                                         | A keyword or handle.                        |
|           | <code>max-name-size</code>                                                                                                | An integer.                                 |
|           | <code>max-names</code>                                                                                                    | An integer.                                 |
|           | <code>errorp</code>                                                                                                       | A boolean.                                  |
|           | <code>value-function</code>                                                                                               | A function designator or <code>nil</code> . |

|             |                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <code>subsubkeys</code> | A list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Description |                         | The function <code>collect-registry-subkeys</code> returns a list of names which are subsubkeys of <i>subkey</i> under the key <i>root</i> .<br><i>subkey</i> and <i>root</i> are interpreted as described for <code>create-registry-key</code> . The default value of <i>root</i> is <code>:user</code> .<br><i>max-name-size</i> specifies the maximum length of the returned name. If the name is longer than this, an error is signalled. The default value of <i>max-name-size</i> is 256.<br><i>max-names</i> specifies the maximum number of names returned. Names after this number are ignored. The default value of <i>max-names</i> is <code>most-positive-fixnum</code> .<br>If <i>value-function</i> is non-nil, it should be a function with signature<br><br><code>value-function handle subsubkey-name =&gt; name, collectp</code> |
|             |                         | <i>value-function</i> is funcalled for each subsubkey with the handle of <i>subkey</i> and the name of the subsubkey. If <i>collectp</i> is non-nil then <i>name</i> is collected into the list <i>subsubkeys</i> to return from <code>collect-registry-subkeys</code> . Otherwise it is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|             |                         | If <i>value-function</i> is <code>nil</code> , then the returned <i>subsubkeys</i> is a list of strings naming all (subject to <i>max-names</i> ) of the subsubkeys. The default value of <i>value-function</i> is <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|             |                         | If an error occurs opening <i>subkey</i> and <i>errorp</i> is true then an error is signalled. Otherwise, <i>subsubkeys</i> is returned as <code>nil</code> if <i>subkey</i> could not be opened. The default value of <i>errorp</i> is <code>t</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Description | <p>The function <code>collect-registry-values</code> returns an alist of all of the values of <code>subkey</code> under the key <code>root</code>. <code>subkey</code> and <code>root</code> are interpreted as described for <code>create-registry-key</code>. The default value of <code>root</code> is <code>:user</code>. <code>max-name-size</code> specifies the maximum length of the returned name. If the name is longer than this, an error is signalled. The default value of <code>max-name-size</code> is 256. <code>max-buffer-size</code> specifies the maximum length in bytes of the data. If the data is longer than this, an error is signalled. The default value of <code>max-buffer-size</code> is 1024. If <code>value-function</code> is <code>nil</code>, the returned <code>values-alist</code> is an association list containing pairs <code>(name . data)</code> consisting of the names and data of the values of <code>subkey</code>. <code>expected-type</code> controls how certain types are converted to Lisp objects as described for <code>enum-registry-value</code>. The default value of <code>expected-type</code> is <code>t</code>. If <code>value-function</code> is non-nil, it should be a function with signature</p> |                                          |

```
value-function handle subsubkey-name-and-value => name-and-
value, collectp
```

*value-function* is funcalled for each subsubkey with the handle of *subkey* and a cons of the name and value of the subsubkey. If *collectp* is non-nil then *name-and-value* is collected into the alist *values-alist* to return from **collect-registry-values**. Otherwise *name-and-value* is ignored.

If an error occurs and *errorp* is true, then an error is signalled. Otherwise, *values-alist* is returned as nil if *subkey* could not be opened at all or contains nil for the data of any particular pair that cannot be read. The default value of *errorp* is t.

| Description | <p>The function <code>create-registry-key</code> creates a new registry key named <i>subkey</i> under the parent key <i>root</i>. If the key already exists, it is opened and returned.</p> <p><i>subkey</i> is a string specifying a path from a root. Each component of the path is separated by a backslash. Use "" to denote the null path (that is, the root).</p> <p><i>class</i> can be used to specify the class of the key if it is created.</p> <p><i>root</i> should be a handle to an open registry key (for example a key returned by <code>create-registry-key</code> or <code>open-registry-key</code> or one of the keywords <code>:classes</code>, <code>:user</code>, <code>:local-machine</code> and <code>:users</code> which represent the standard top level roots in the registry. The default value of <i>root</i> is <code>:user</code>.</p> <p>If <i>access</i> is <code>:read</code>, then the key is created with <code>KEY_READ</code> permissions. If <i>access</i> is <code>:write</code>, then the key is created with <code>KEY_WRITE</code> permissions. If <i>access</i> is an integer, then the value <i>access</i> specifies the desired Win32 access rights. The default value of <i>access</i> is <code>:read</code>.</p> <p>The return values on success are the handle of the new key and a keyword <code>:created-new-key</code> or <code>:opened-existing-key</code> indicating whether a new key was created or opened.</p> <p>If an error occurs and <i>errorp</i> is true then an error is signalled. Otherwise, the return values are <code>nil</code>, <code>nil</code> and the Windows <i>error-code</i>. The default value of <i>errorp</i> is <code>t</code>.</p> |                                             |

| Description | <p>The function <code>delete-registry-key</code> deletes the registry key named <i>subkey</i> under the parent key <i>root</i>.<br/><i>subkey</i> and <i>root</i> are interpreted as described for <code>create-registry-key</code>. The default value of <i>root</i> is <code>:user</code>.<br/>The value <code>t</code> is returned if the key is deleted successfully.<br/>If an error occurs and <i>errorp</i> is true then an error is signalled. Otherwise, the return values are <code>nil</code> and the Windows <i>error-code</i>. The default value of <i>errorp</i> is <code>t</code>.</p> |                                             |

|             | <i>error-code</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | An integer error code or <code>nil</code> . |
| Description | <p>The function <code>enum-registry-value</code> allows the values of subkey under the key <i>root</i> to be enumerated.</p> <p><i>subkey</i> and <i>root</i> are interpreted as described for <code>create-registry-key</code>. The default value of <i>root</i> is <code>:user</code>.</p> <p><i>index</i> specifies which value to return, with 0 being the first item.</p> <p><i>max-name-size</i> specifies the maximum length of the returned name. If the name is longer than this, an error is signalled. The default value of <i>max-name-size</i> is 256.</p> <p><i>max-buffer-size</i> specifies the maximum length in bytes of the value. The value is longer than this, an error is signalled. The default value of <i>max-buffer-size</i> is 1024.</p> <p>If the value exists (that is, <i>index</i> is not too large), then the return values are the name, data type and data associated with the value in the registry. The argument <i>expected-type</i> con-</p> |                                             |

trols how certain data types are converted to Lisp objects as follows:

Table 42.1 Conversion of registry values to Lisp objects

| <i>data-type</i>                    | <i>expected-type</i>      | Description of converted data                         |
|-------------------------------------|---------------------------|-------------------------------------------------------|
| <code>:string</code>                | <code>:lisp-object</code> | String made with <code>read-from-string</code>        |
| <code>:string</code>                | Not supplied              | String, exactly as in the registry                    |
| <code>:environment-string</code>    | <code>:string</code>      | String, exactly as in the registry                    |
| <code>:environment-string</code>    | Not supplied              | String, environment variables expanded                |
| <code>:integer</code>               | Not supplied              | Integer                                               |
| <code>:little-endian-integer</code> | Not supplied              | Integer                                               |
| <code>:binary</code>                | Not supplied              | A newly allocated foreign object                      |
| <code>:binary</code>                | <code>:lisp-object</code> | Vector, element type ( <code>unsigned-byte 8</code> ) |

The default value of *expected-type* is `t`.

If an error occurs and `errorp` is true, then an error is signalled. Otherwise, the return values are `nil`, `nil`, `nil` and the Windows *error-code*. The default value of `errorp` is `t`.

| Description              | <p>The function <code>open-registry-key</code> opens a registry key named <i>subkey</i> under the parent key <i>root</i>.</p> <p><i>subkey</i> and <i>root</i> are interpreted as described for <code>create-registry-key</code>. If <i>subkey</i> is an empty string, then the <i>root</i> key is returned. The default value of <i>root</i> is <code>:user</code>.</p> <p>If <i>access</i> is <code>:read</code>, then it opens the key with <code>KEY_READ</code> permissions. If <i>access</i> is <code>:write</code>, then it opens the key with <code>KEY_WRITE</code> permissions. If <i>access</i> is an integer, then the value <i>access</i> specifies the desired Win32 access rights. If <i>access</i> is omitted and <i>root</i> is <code>:user</code>, then <code>open-registry-key</code> uses <code>KEY_ALL_ACCESS</code>. Otherwise it uses <code>KEY_READ</code>.</p> <p>The return value on success is the <i>handle</i> of the opened key.</p> <p>If an error occurs and <i>errorp</i> is true, then an error is signalled. Otherwise, the return values are <code>nil</code> and the Windows <i>error-code</i>. The default value of <i>errorp</i> is <code>t</code>.</p> |                                                                                                                      |

| Description             | The function <code>query-registry-key-info</code> returns a plist of information about the open registry key handle <code>key</code> . The elements of the plist <code>info</code> are:<br><br><code>:class</code> A string naming the class of the key, if any.<br><code>:subkeys-count</code> An integer giving the number of subkeys.<br><code>:subkey-max-len</code><br>An integer giving the length of the longest subkey name.<br><code>:class-name-max-len</code><br>An integer giving the length of the longest class name.<br><code>:values-count</code> An integer giving the number of values.<br><code>:value-max-len</code> An integer giving the length of the longest value name.<br><code>:max-data-len</code> An integer giving the length of the longest value data.<br><code>:security-len</code> An integer giving the length of the security descriptor. |

| Description                | <p>The function <code>query-registry-value</code> returns the value associated with <code>name</code> in <code>subkey</code> under the key <code>root</code>. <code>subkey</code> and <code>root</code> are interpreted as described for <code>create-registry-key</code>. If <code>subkey</code> is an empty string, then the <code>root</code> key is returned. The default value of <code>root</code> is <code>:user</code>.</p> <p>If the value exists, then the return values are the data and true. <code>expected-type</code> controls how certain types are converted to the Lisp object <code>data</code> as described for <code>enum-registry-value</code>. The default value of <code>expected-type</code> is <code>t</code>.</p> <p>If an error occurs and <code>errorp</code> is true then an error is signalled. Otherwise, the return values are <code>nil</code>, <code>nil</code> and the Windows <code>error-code</code>. The default value of <code>errorp</code> is <code>t</code>.</p> |                     |                                          |                       |                                            |                         |                                             |                            |                               |                     |            |

| Description                  | <p>The function <code>registry-key-exists-p</code> checks whether the registry key named <i>subkey</i> can be opened under the parent key <i>root</i> with the supplied <i>access</i> permissions.</p> <p><i>subkey</i> and <i>root</i> are interpreted as described for <code>create-registry-key</code>. The default value of <i>root</i> is <code>:user</code>.</p> <p>If <i>access</i> is <code>:read</code>, then it opens the key with <code>KEY_READ</code> permissions. If <i>access</i> is <code>:write</code>, then it opens the key with <code>KEY_WRITE</code> permissions. If <i>access</i> is an integer, then the value <i>access</i> specifies the desired Win32 access rights. If <i>access</i> is omitted and <i>root</i> is <code>:user</code>, then <code>registry-key-exists-p</code> uses <code>KEY_ALL_ACCESS</code>. Otherwise it uses <code>KEY_READ</code>.</p> <p><code>registry-key-exists-p</code> closes the key before returning, but the return value is <code>t</code> if the key could actually be opened and <code>nil</code> otherwise.</p> |               |                                          |             |                      |               |                        |

| <code>error-code</code>    | An integer error code or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                     |                                          |                       |                                            |                         |                                             |                            |                               |                     |            |
| Description                | <p>The function <code>registry-value</code> returns the value associated with <code>name</code> in <code>subkey</code> under the key <code>root</code>.</p> <p><code>subkey</code> and <code>root</code> are interpreted as described for <code>create-registry-key</code>. The default value of <code>root</code> is <code>:user</code>.</p> <p>If the value exists, then the return values are the data and true. <code>expected-type</code> controls how certain types are converted to Lisp objects as described for <code>enum-registry-value</code>. The default value of <code>expected-type</code> is <code>t</code>.</p> <p>If an error occurs and <code>errorp</code> is true then an error is signalled. Otherwise, the return values are <code>nil</code>, <code>nil</code> and the Windows <code>error-code</code>. The default value of <code>errorp</code> is <code>t</code>.</p> <p>The function <code>(setf registry-value)</code> sets the value associated with <code>name</code> in <code>subkey</code> under the key <code>root</code>, creating the subkey if necessary. The default value of <code>root</code> is <code>:user</code>.</p> |                     |                                          |                       |                                            |                         |                                             |                            |                               |                     |            |

| <code>data</code>          | A Lisp object.                                                                                                                                                                                                                                                                                                                                                                                                                                    |                   |                |                     |                                          |                   |                                            |                   |                      |                            |                 |                     |            |
| <code>subkey</code>        | A string specifying the name of the key.                                                                                                                                                                                                                                                                                                                                                                                                          |                   |                |                     |                                          |                   |                                            |                   |                      |                            |                 |                     |            |
| <code>name</code>          | A string specifying the name of the value.                                                                                                                                                                                                                                                                                                                                                                                                        |                   |                |                     |                                          |                   |                                            |                   |                      |                            |                 |                     |            |
| <code>root</code>          | A keyword or handle.                                                                                                                                                                                                                                                                                                                                                                                                                              |                   |                |                     |                                          |                   |                                            |                   |                      |                            |                 |                     |            |
| <code>expected-type</code> | A keyword or t.                                                                                                                                                                                                                                                                                                                                                                                                                                   |                   |                |                     |                                          |                   |                                            |                   |                      |                            |                 |                     |            |
| <code>errorp</code>        | A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                        |                   |                |                     |                                          |                   |                                            |                   |                      |                            |                 |                     |            |
| Values                     | <code>error-code</code> An integer error code or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                               |                   |                |                     |                                          |                   |                                            |                   |                      |                            |                 |                     |            |
| Description                | <p>The function <code>set-registry-value</code> sets the value associated with <i>name</i> in <i>subkey</i> under the key <i>root</i>.</p> <p><i>subkey</i> and <i>root</i> are interpreted as described for <code>create-registry-key</code>. The default value of <i>root</i> is <code>:user</code>.</p> <p>The stored value is derived from <i>data</i>, converted according to <i>expected-type</i> as follows:</p>                           |                   |                |                     |                                          |                   |                                            |                   |                      |                            |                 |                     |            |

Table 42.2 Conversion of Lisp objects to registry values

| Lisp data  | <i>expected-type</i>      | Registry type                                                             |
|------------|---------------------------|---------------------------------------------------------------------------|
| A string   | <code>:string</code>      | <code>REG_SZ</code> exactly as in <i>data</i>                             |
| Lisp value | <code>:lisp-object</code> | <code>REG_SZ</code> made with <code>prin1-to-string</code> of <i>data</i> |

Table 42.2 Conversion of Lisp objects to registry values

| Lisp data         | <i>expected-type</i>  | Registry type                                                          |
|-------------------|-----------------------|------------------------------------------------------------------------|
| An integer        | <code>:integer</code> | <code>REG_DWORD</code> containing <i>data</i>                          |
| A foreign pointer | <code>:binary</code>  | <code>REG_BINARY</code> containing bytes of one element at the pointer |
| An array          | <code>:binary</code>  | <code>REG_BINARY</code> containing bytes from the array                |

The default value of *expected-type* is `t`.

If an error occurs and *errorp* is true then an error is signalled.  
The default value of *errorp* is `t`.

## with-registry-key *Macro*

Summary      Runs code with an open registry key handle.

Package      `win32`

Signature      `with-registry-key (handle subkey &key root access errorp)  
&body body => values`

|           |                     |                                          |
|-----------|---------------------|------------------------------------------|
| Arguments | <code>handle</code> | A variable name.                         |
|           | <code>subkey</code> | A string specifying the name of the key. |
|           | <code>root</code>   | A keyword or handle.                     |
|           | <code>access</code> | An integer or keyword.                   |

|             |               |                                                                                                                                                                                                                                                                               |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>errorp</i> | A boolean.                                                                                                                                                                                                                                                                    |
| Values      | <i>values</i> | The values returned by <i>body</i> .                                                                                                                                                                                                                                          |
| Description |               | The macro <b>with-registry-key</b> evaluates <i>body</i> with the variable <i>handle</i> bound to the registry key handle opened as if by calling<br><br><code>(open-registry-key <i>subkey</i> :root <i>root</i><br/>:access <i>access</i><br/>:errorp <i>errorp</i>)</code> |
|             |               | <i>subkey</i> and <i>root</i> are interpreted as described for <b>create-registry-key</b> .<br><br>If <i>errorp</i> is <code>nil</code> and <i>subkey</i> cannot be opened then <i>body</i> is not evaluated.                                                                 |

## The DDE client interface

This chapter describes the Dynamic Data Exchange (DDE) client interface which is available in the `WIN32` package. You should use this chapter in conjunction with Chapter 18, “Dynamic Data Exchange”.

The `WIN32` package also includes functions for accessing miscellaneous Microsoft Windows functionality, the registry API, and the DDE server interface. These are documented in separate chapters in this manual.

**Note:** the `WIN32` package is not a supported implementation of the Win32 API. You should not use symbols in the `WIN32` package unless they are documented in this manual. Instead, define your own interfaces to Windows functions as you need - see the *LispWorks Foreign Language Interface User Guide and Reference Manual* for details.

**Note:** this chapter applies only to LispWorks for Windows, and not the UNIX, Linux, x86/x64 Solaris, FreeBSD or Mac OS X platforms.

| <b>dde-advise-start</b> | <i>Function</i>                                                     |
|-------------------------|---------------------------------------------------------------------|
| Summary                 | Sets up an advise loop on a specified data item for a conversation. |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                               |

| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | A boolean.                    |
| Description | <p>The function <code>dde-advise-start</code> sets up an advise loop for the data item specified by <i>item</i> on the specified <i>conversation</i>.</p> <p>See “Advise loops” on page 216 for information about DDE advise loops.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                               |
|             | <p>The argument <i>format</i> should be one of the following:</p> <ul style="list-style-type: none"> <li>• A DDE format specifier, consisting of either a standard clipboard format or a registered clipboard format.</li> <li>• A string containing either the name of a standard clipboard format (without the <code>CF_</code> prefix), or the name of a registered clipboard format.</li> <li>• A symbol, in which case its print name is taken to specify the clipboard format.</li> <li>• The keyword <code>:text</code> – the default value of <i>format</i>. The keyword <code>:text</code> is treated specially. If supported by the server it uses the <code>CF_UNICODETEXT</code> clipboard format, otherwise it used the <code>CF_TEXT</code> format.</li> </ul> |                               |

The argument *type* specifies how the response data should be converted to a Lisp object. For text formats, the default value indicates that a Lisp string should be created. The value `:string-list` may be specified to indicate that the return value should be taken as a tab-separated list of strings; in this case the Lisp return value is a list of strings. The default conversation class only supports text formats, unless *type* is specified as `:foreign`, which can be used with any clipboard format. It returns a `clipboard-item` structure, containing a foreign pointer to the data, the data length, and the format identifier.

If *datap* is `t` (the default value), a hot link is established, where the new data is supplied whenever it changes. If *datap* is `nil`, a warm link is established, where the data is not passed, and must be explicitly requested using `dde-request`.

The argument *key* is used to identify this link. If specified as `nil` (the default value), it defaults to the conversation. Multiple links are permitted on a conversation with the same *item* and *format* values, as long as their *key* values differ.

If the link is established, the return value *result* is `t`. If the link could not be established, the behavior depends on the value of *errorp*. If *errorp* is `t` (the default value), LispWorks signals an error. If it is `nil`, the function returns `nil` to indicate failure.

If the link is established, the function *function* is called whenever the data changes. If *function* is `nil` (the default value), then the generic function `dde-client-advise-data` will be called.

The function specified by *function* should have a lambda list similar to the following:

```
key item data &key conversation &allow-other-keys
```

The arguments *key* and *item* identify the link. The argument *data* contains the new data for hot links; for warm links it is `nil`.

| Values      | <i>result</i>                                                                                                                                    | A boolean.                    |
| Description | The function <code>dde-advise-start*</code> is similar to the <code>dde-advise-start</code> , and sets up an advise loop for the data item       |                               |

specified by *item* on a conversation recognizing the *service/topic* pair.

See **dde-advise-start** for information on DDE advise loops and the *format*, *type*, and *datap* arguments.

The argument *key* is used to identify this link. If specified as **nil** (the default value), it defaults to the conversation. Multiple links are permitted on a conversation with the same *item* and *format* values, as long as their *key* values differ.

If the link is established, the return value *result* is **t**. If the link could not be established, the behavior depends on the value of *errorp*. If *errorp* is **t** (the default value), LispWorks signals an error. If it is **nil**, the function returns **nil** to indicate failure.

If the link is established, the function *function* will be called whenever the data changes. If *function* is **nil** (the default value), the generic function **dde-client-advise-data** will be called.

The function specified by *function* should have a lambda list similar to the following:

**key item data &key conversation &allow-other-keys**

The arguments *key* and *item* identify the link. The argument *data* contains the new data for hot links; for warm links it is **nil**.

| Description | <p>The function <code>dde-advise-stop</code> removes a particular link from <i>conversation</i> specified by <i>item</i>, <i>format</i> and <i>key</i>. If <i>key</i> is the last key for the <i>item/format</i> pair, the advise loop for the pair is terminated.</p> <p>See “Advise loops” on page 216 for information about DDE advise loops.</p> <p>If <i>disconnectp</i> is <code>t</code>, and the last advise loop for the conversation is terminated, the conversation is disconnected.</p> <p>Attempting to remove a link that does not exist raises an error, unless <i>no-advise-ok</i> is <code>t</code>.</p> <p>If this function succeeds, it returns <code>t</code>. If it fails, the behavior depends on the value of <i>errorp</i>. If <i>errorp</i> is <code>t</code> (the default value), LispWorks signals an error. If <i>errorp</i> is <code>nil</code>, the function returns <code>nil</code> to indicate failure.</p> |                               |

|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>dde-advise-stop*</code> is similar to the function <code>dde-advise-stop</code> , and removes a particular link from a conversation specified by the <code>service/topic</code> pair indicated by <code>item</code> , <code>format</code> and <code>key</code> . If <code>key</code> is the last key for the <code>item/format</code> pair, the advise loop for the pair is terminated. |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

See “Advise loops” on page 216 for information about DDE advise loops.

If `disconnectp` is `t` (the default value), and the last advise loop for the conversation is terminated, the conversation is disconnected.

If this function succeeds, it returns `t`. If it fails, the behavior depends on the value of `errorp`. If `errorp` is `t` (the default value), LispWorks signals an error. If `errorp` is `nil`, the function returns `nil` to indicate failure.

**dde-client-advise-data***Generic Function*

## Summary

Called when data changes in an advise loop.

## Package

`win32`

## Signature

`dde-client-advise-data key item data &key &allow-other-keys`

## Arguments

`key` An object.

`item` A string or symbol.

`data` A string.

## Values

None.

## Description

The generic function `dde-client-advise-data` is the default function called when an advise loop informs a client that the data monitored by the loop has changed. By default it does nothing, but it may be specialized on the object used as the key in `dde-advise-start` or `dde-advise-start*`, or on a client conversation class if the default `key` is used.

See “Advise loops” on page 216 for information about DDE advise loops.

| <i>class</i>       | The class of the conversation object to create.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                     |              |                     |              |                                                 |               |            |
| <i>errorp</i>      | A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                     |              |                     |              |                                                 |               |            |
| Values             | <i>object</i><br>A conversation object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                     |              |                     |              |                                                 |               |            |
| Description        | <p>The function <code>dde-connect</code> attempts to create a conversation with a DDE server. If <code>server</code> names a client service registered with <code>define-dde-client</code>, the registered service name is used as the DDE service name. If <code>server</code> is any other symbol, the print name of the symbol is used as the DDE service name. If <code>server</code> is a string, that string is used as the DDE service name.</p> <p>The <code>topic</code> argument specifies the DDE topic name to be used in the conversation. If it is a symbol, the symbol's print name is used. If it is a string, the string is used.</p> <p>The <code>class</code> argument specifies the class of the conversation object to create. It must be a subclass of <code>dde-client-conversation</code>, or <code>nil</code>. If it is <code>nil</code> (the default value), then a conversation of class <code>dde-client-conversation</code> is created, unless <code>server</code> names a client service registered with <code>define-dde-client</code>, in which case the registered class (if any) is used.</p> <p>On executing successfully, this function returns a conversation object. If unsuccessful, the behavior depends on the</p> |                |                     |              |                     |              |                                                 |               |            |

value of *errorp*. If *errorp* is `t` (the default value), then an error is raised. If *errorp* is false, the function returns `nil`.

Note that conversation objects may only be used within the thread (lightweight process) in which they were created.

### **dde-disconnect** *Function*

Summary      Disconnects a conversation object.

Package      `win32`

Signature      **dde-disconnect** *conversation* => *result*

Arguments      *conversation*      A conversation object.

Values      *result*      *A boolean*.

Description      The function **dde-disconnect** disconnects the conversation object. The conversation may no longer be used. If the conversation disconnects successfully, `t` is returned.

### **dde-execute** *Function*

Summary      An alternative syntax for **dde-execute-command**.

Package      `win32`

Signature      **dde-execute** *conversation command &rest {args}\* => result*

Arguments      *conversation*      A conversation object.

*This chapter applies only to LispWorks for Windows*

|             | <i>command</i> | A string or symbol.                                                                                                                                                                                                                                                                                                                                        |
|             | <i>args</i>    | An argument.                                                                                                                                                                                                                                                                                                                                               |
| Values      | <i>result</i>  | A boolean.                                                                                                                                                                                                                                                                                                                                                 |
| Description |                | The function <code>dde-execute</code> provides an alternative syntax for <code>dde-execute-command</code> . Unlike <code>dde-execute-command</code> , <code>dde-execute</code> takes the arguments for <i>command</i> as a sequence of <i>args</i> following <code>&amp;rest</code> , and does not have an argument for specifying how to handle an error. |

|             | <i>command</i>                                                                                                                                                                                                                 | A string or symbol. |
|             | <i>args</i>                                                                                                                                                                                                                    | An argument.        |
| Values      | <i>result</i>                                                                                                                                                                                                                  | A boolean.          |
| Description | The function <code>dde-execute*</code> provides an alternative syntax for <code>dde-execute-command*</code> . Unlike <code>dde-execute-command*</code> , <code>dde-execute*</code> takes the arguments for <i>command</i> as a |                     |

sequence of `args` following `&rest`, and does not have any arguments for specifying how to handle errors.

## dde-execute-command

*Function*

Summary      Sends a command string to a specified conversation.

Package      `win32`

Signature      `dde-execute-command conversation command arg-list &key errorp => result`

Arguments      `conversation`      A conversation object.

`command`      A string or symbol.

`arg-list`      A list of strings, integers, and floats.

`errorp`      A boolean.

Values      `result`      A boolean.

Description      The function `dde-execute-command` sends a command string to the conversation specified by `conversation`. The command string consists of `command` and `arg-list`, which are combined using the appropriate argument-marshalling conventions. By default, the syntax is

```
[command(arg1,arg2,...)]
```

On success, this function returns a result of `t`. On failure, the behavior depends on the value of the `errorp` argument. If `errorp` is `t` (the default value), LispWorks signals an error. If it is `nil`, the function returns `nil` to indicate failure.

**dde-execute-command\*** *Function*

Summary      Sends a command string to a specified service on a given topic.

Package      **win32**

Signature      **dde-execute-command\* service topic command arg-list &key errorp connect-error-p new-conversation-p => result**

Arguments      *service*      A string or symbol.

*topic*      A string or symbol.

*command*    A string or symbol.

*arg-list*   A list of strings, integers, and floats.

*errorp*     A boolean.

*connect-error-p*    A boolean.

*new-conversation-p*

                  A boolean.

Values      *result*      A boolean.

Description      The function **dde-execute-command\*** is similar to **dde-execute-command**, and sends a command string to the server specified by *service* on a topic given by *topic*. The command string consists of *command* and *arg-list*, which are combined using the appropriate argument-marshalling conventions. By default, the syntax is

`[command(arg1,arg2,...)]`

If *server* names a client service registered with `define-dde-client`, the registered service name is used as the DDE service name. If *server* is any other symbol, the print name of the symbol is used as the DDE service name. If *server* is a string, that string is used as the DDE service name.

The *topic* argument specifies the DDE topic name to be used in the conversation. If it is a symbol, the symbol's print name is used. If it is a string, the string is used.

If necessary, the function `dde-execute-command*` creates a conversation for the duration of the transaction, but if a suitable conversation already exists, the transaction is executed over that conversation. Hence, if several transactions will be made with the same service and *topic*, placing them inside a `with-dde-conversation` prevents a new conversation being established for each transaction.

If *new-conversation-p* is set to `t` a new conversation is always established for the transaction. This new conversation is always automatically disconnected when the transaction is completed.

If *connect-error-p* is `t` (the default value) and a conversation cannot be established, then LispWorks signals an error. If it is `nil`, `dde-execute-command*` returns `nil` if a conversation cannot be established. This allows the caller to distinguish between the cases when the server is not running, and when the server is running but the transaction fails.

Upon success, this function returns a result of `t`. On failure, the behavior depends on the value of the *errorp* argument. If *errorp* is `t` (the default value), LispWorks signals an error. If it is `nil`, the function returns `nil` to indicate failure.

No processing of the string is performed.<br><br>On success, this function returns <code>t</code> . On failure, the behavior depends on the value of the <i>errorp</i> argument. If <i>errorp</i> is <code>t</code> (the default value), LispWorks signals an error. If it is <code>nil</code> , the function returns <code>nil</code> to indicate failure. |                        |

| Description | <p>The function <code>dde-execute-string*</code> is similar to <code>dde-execute-string</code>, in that it issues an execute transaction consisting of the string <code>command</code>. However, the conversation across which <code>command</code> is issued is managed automatically. No processing of the string is performed.</p> <p>If <code>server</code> names a client service registered with <code>define-dde-client</code>, the registered service name is used as the DDE service name. If <code>server</code> is any other symbol, the print name of the symbol is used as the DDE service name. If <code>server</code> is a string, that string is used as the DDE service name.</p> <p>The <code>topic</code> argument specifies the DDE topic name to be used in the conversation. If it is a symbol, the symbol's print name is used. If it is a string, the string is used.</p> <p>If necessary, the function <code>dde-execute-string*</code> will create a conversation for the duration of the transaction, but if a suitable conversation already exists, the transaction will be executed over that conversation. Hence, if several transactions will be made with the same <code>service</code> and <code>topic</code>, placing them inside a <code>with-dde-conversation</code> prevents a new conversation being established for each transaction.</p> |                     |

If *new-conversation-p* is set to `t` a new conversation is always established for the transaction. This new conversation is always automatically disconnected when the transaction is completed.

If *connect-error-p* is `t` (the default value), then LispWorks signals an error if a conversation cannot be established. If it is `nil`, `dde-execute-string*` returns `nil` if a conversation cannot be established. This allows the caller to distinguish between the cases when the server is not running, and when the server is running but the transaction fails.

Upon success, the function returns `t`. On failure, the behavior depends on the value of the *errorp* argument. If *errorp* is `t` (the default value), LispWorks signals an error. If it is `nil`, the function returns `nil` to indicate failure.

## `dde-item`

## *Accessor*

Summary

An accessor which can perform a request transaction or a poke transaction.

Package

`win32`

Signature

`dde-item conversation item &key format type errorp => result`

Arguments

*conversation*      A conversation object.

*item*                A string or symbol.

*format*             A clipboard format specifier.

*type*                A keyword.

*errorp*             A boolean.

Values      `result`      A boolean.

Description      The accessor `dde-item` performs a request transaction when read. It performs a poke transaction when set.

To illustrate, the following `dde-request` command

```
(dde-request conversation item :format format :type type
 :errorp errorp)
```

can also be issued using `dde-item` as follows:

```
(dde-item conversation item :FORMAT format :TYPE type
 :ERRORP errorp)
```

Similarly, the following `dde-poke` command

```
(dde-poke conversation item data :format format :type type
 :errorp errorp)
```

can be issued using `dde-item` as follows:

```
(setf (dde-item conversation item :format format :type type
 :errorp errorp) data)
```

except that the *format* always returns *data*.

Upon success, this function returns a *result* of `t`. On failure, the behavior depends on the value of the *errorp* argument. If *errorp* is `t` (the default value), LispWorks signals an error. If it is `nil`, the function returns `nil` to indicate failure.

## **dde-item\*** *Accessor*

Summary      An accessor which can perform a request transaction or a poke transaction on an automatically managed conversation.

Package      `win32`

Signature      **dde-item\*** *service topic item &key format type errorp connect-error-p new-conversation-p => result*

Arguments      *service*            A string or symbol.  
*topic*            A string or symbol.  
*item*            A string or symbol.  
*format*          A clipboard format specifier.  
*type*            A keyword.  
*errorp*          A boolean.  
*connect-error-p*    A boolean.  
  
*new-conversation-p*  
                  A boolean.

Values      *result*            A boolean.

Description      The accessor **dde-item\*** is similar to **dde-item**, and performs a request transaction when read. It performs a poke transaction when set.

To illustrate, the following **dde-request\*** command

```
(dde-request* service topic item :format format :type type
 :errorp errorp connect-error-p new-conversation-p)
```

can also be issued using **dde-item\*** as follows:

```
(dde-item* service topic item :FORMAT format :TYPE type
 :ERRORP errorp connect-error-p new-conversation-p)
```

Similarly, the following **dde-poke\*** command

```
(dde-poke* conversation item data :format format :type type
 :errorp errorp connect-error-p new-conversation-p)
```

can be issued using **dde-item\*** as follows:

```
(setf (dde-item* conversation item :format format :type type
 :errorp errorp connect-error-p new-conversation-p) data)
```

except that the *format* always returns *data*.

If necessary, the accessor `dde-item*` creates a conversation for the duration of the transaction, but if a suitable conversation already exists, the transaction is executed over that conversation. If you need to make several transactions with the same *service* and *topic*, placing them inside a `with-dde-conversation` prevents a new conversation being established for each transaction.

If *new-conversation-p* is set to `t` a new conversation is always established for the transaction. This new conversation is always automatically disconnected when the transaction is completed.

If *connect-error-p* is `t` (the default value), then LispWorks signals an error if a conversation cannot be established. If it is `nil`, `dde-item*` returns `nil` if a conversation cannot be established. This allows the caller to distinguish between the cases when the server is not running, and when the server is running but the transaction fails.

On success, the function returns `t`. On failure, the behavior depends on the value of the *errorp* argument. If *errorp* is `t` (the default value), LispWorks signals an error. If it is `nil`, the function returns `nil` to indicate failure.

## `dde-poke`

### *Function*

Summary

Issues a poke transaction on a conversation, to set the value of a specified item.

Package

`win32`

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                               |

|             | <i>format</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A clipboard format specifier. |
|             | <i>type</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | A keyword.                    |
|             | <i>errorp</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A boolean.                    |
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | A boolean.                    |
| Description | The function <code>dde-poke</code> issues a poke transaction on <i>conversation</i> to set the value of the item specified by <i>item</i> to the value specified by <i>data</i> . The argument <i>item</i> should be a string, or a symbol. If it is a symbol its print name is used.<br><br>The argument <i>format</i> should be one of the following:                                                                                                                                                                                                                                                                                                                                            |                               |
|             | <ul style="list-style-type: none"><li>• A DDE format specifier, consisting of either a standard clipboard format or a registered clipboard format.</li><li>• A string containing either the name of a standard clipboard format (without the <code>CF_</code> prefix), or the name of a registered clipboard format.</li><li>• A symbol, in which case its print name is taken to specify the clipboard format.</li><li>• The keyword <code>:text</code>. This is the default value.</li></ul> <p>The keyword <code>:text</code> is treated specially. If supported by the server it uses the <code>CF_UNICODETEXT</code> clipboard format, otherwise it used the <code>CF_TEXT</code> format.</p> |                               |
|             | For text transactions, the default value of <i>type</i> indicates that <i>data</i> is a Lisp string to be used. If <i>type</i> is <code>:string-list</code> , then <i>data</i> is taken to be a list of strings, and is sent as a tab-separated string.                                                                                                                                                                                                                                                                                                                                                                                                                                            |                               |

Alternatively, *data* can be a `clipboard-item` structure, containing a foreign pointer to the data to send and the length of the data. In this case the *type* argument is ignored.

On success, this function returns `t`. On failure, the behavior depends on the value of the *errorp* argument. If *errorp* is `t` (the default value), LispWorks signals an error. If it is `nil`, the function returns `nil` to indicate failure.

| Description | <p>The function <code>dde-poke*</code> is the same as <code>dde-poke</code>, except that conversations are managed automatically. The function issues a poke transaction to set the value of the item specified by <i>item</i> to the value specified by <i>data</i>. The argument <i>item</i> should be a string, or a symbol. If it is a symbol its print name is used.</p> <p>If <i>server</i> names a client service registered with <code>define-dde-client</code>, the registered service name is used as the DDE service name. If <i>server</i> is any other symbol, the print name of the symbol is used as the DDE service name. If <i>server</i> is a string, that string is used as the DDE service name.</p> <p>The <i>topic</i> argument specifies the DDE topic name to be used in the conversation. If it is a symbol, the symbol's print name is used. If it is a string, the string is used.</p> <p>For information on the <i>format</i>, <i>type</i>, and <i>errorp</i> arguments, see <code>dde-poke</code>.</p> <p>If necessary, the function <code>dde-poke*</code> creates a conversation for the duration of the transaction, but if a suitable conversation already exists, the transaction is executed over that conversation. Hence, if several transactions are made with the same <i>service</i> and <i>topic</i>, placing them inside a <code>with-dde-conversation</code> prevents a new conversation being established for each transaction.</p> <p>If <i>new-conversation-p</i> is set to <code>t</code> a new conversation is always established for the transaction. This new conversation is always automatically disconnected when the transaction is completed.</p> <p>If <i>connect-error-p</i> is <code>t</code> (the default value), LispWorks signals an error if a conversation cannot be established. If it is <code>nil</code>, <code>dde-poke*</code> returns <code>nil</code> if a conversation cannot be established. This allows the caller to distinguish between the cases when</p> |            |

the server is not running, and when the server is running but the transaction fails.

| Description | The function <code>dde-request</code> issues a request transaction on <i>conversation</i> for the specified <i>item</i> . The argument <i>item</i> should be a string, or a symbol. If it is a symbol its print name is used.<br><br>The argument <i>format</i> should be one of the following: |                                                                                                                                                              |
|             |                                                                                                                                                                                                                                                                                                 | <ul style="list-style-type: none"><li>• A DDE format specifier, consisting of either a standard clipboard format or a registered clipboard format.</li></ul> |

- A string containing either the name of a standard clipboard format (without the `CF_` prefix), or the name of a registered clipboard format.
- A symbol, in which case its print name is taken to specify the clipboard format.
- The keyword `:text`. This is the default value.

The keyword `:text` is treated specially. If supported by the server it uses the `CF_UNICODETEXT` clipboard format, otherwise it used the `CF_TEXT` format.

The default conversation class only supports text formats, unless `type` is specified as `:foreign`. The argument `type` specifies how the response data should be converted to a Lisp object. For text formats, the default value indicates that a Lisp string should be created. The value `:string-list` may be specified for `type` to indicate that the return value should be taken as a tab-separated list of strings; in this case the Lisp return value is a list of strings. The value `:foreign` can be used with any clipboard format. It returns a `clipboard-item` structure, containing a foreign pointer to the data, the data length, and the format identifier.

This function returns two values, `result` and `successp`. If successful, `result` is the return value of the transaction (which may be `nil` in the case of `:string-list`), and `successp` is true to indicate success.

On failure, the result of the function depends on the `errorp` argument. If `errorp` is `t` (the default), the function signals an error. If `errorp` is `nil`, the function returns `(values nil nil)`.

| Values                    | <i>result</i> The return value of the transaction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                     |              |                     |             |                     |               |                               |             |            |               |            |                        |            |                           |            |
| Description               | <p>The function <code>dde-request*</code> is similar to <code>dde-request</code>, except that conversations are managed automatically. The function issues a request transaction for the specified <i>item</i>. The argument <i>item</i> should be a string, or a symbol. If it is a symbol its print name is used.</p> <p>If <i>server</i> names a client service registered with <code>define-dde-client</code>, the registered service name is used as the DDE service name. If <i>server</i> is any other symbol, the print name of the symbol is used as the DDE service name. If <i>server</i> is a string, that string is used as the DDE service name.</p> |                |                     |              |                     |             |                     |               |                               |             |            |               |            |                        |            |                           |            |

The *topic* argument specifies the DDE topic name to be used in the conversation. If it is a symbol, the symbol's print name is used. If it is a string, the string is used.

For information on the *format*, *type*, and *errorp* arguments see **dde-request**.

If necessary, the function **dde-request\*** will create a conversation for the duration of the transaction, but if a suitable conversation already exists, the transaction will be executed over that conversation. Hence, if several transactions will be made with the same *service* and *topic*, placing them inside a **with-dde-conversation** prevents a new conversation being established for each transaction.

If *new-conversation-p* is set to **t** a new conversation is always established for the transaction. This new conversation is always automatically disconnected when the transaction is completed.

If *connect-error-p* is **t** (the default value), then LispWorks signals an error if a conversation cannot be established. If it is **nil**, **dde-request\*** returns **nil** if a conversation cannot be established. This allows the caller to distinguish between the cases when the server is not running, and when the server is running but the transaction fails.

| Description | <p>The macro <code>define-dde-client</code> defines a mapping from the symbol <code>name</code> to the DDE service name with which to establish a conversation, and the conversation class to use for this conversation. The argument <code>service</code> is a string which names the DDE service. It defaults to the print-name of <code>name</code>. The argument <code>class</code> is a subclass of <code>dde-client-conversation</code> which is used for all conversations with this service. It defaults to <code>dde-client-conversation</code>. Specifying a subclass allows various aspects of the behavior of the conversation to be specialized.</p> <p>Note that it is generally not necessary to register client services unless a specialized conversation type is required. However, it is sometimes convenient to register a client service in order to allow the service name to be changed in the future.</p> <p>If the macro executes successfully, the <code>name</code> of the DDE service is returned.</p> |                                                      |

| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | A boolean.             |
| Description | <p>The macro <code>with-dde-conversation</code> dynamically binds a conversation with a server across the scope of a body of code specified by <i>body</i>. The argument <i>conv</i> is bound to a conversation with the server specified by <i>service</i>, and the topic specified by <i>topic</i>.</p> <p>If <i>server</i> names a client service registered with <code>define-dde-client</code>, the registered service name is used as the DDE service name. If <i>server</i> is any other symbol, the print name of the symbol is used as the DDE service name. If <i>server</i> is a string, that string is used as the DDE service name.</p> <p>The <i>topic</i> argument specifies the DDE topic name to be used in the conversation. If it is a symbol, the symbol's print name is used. If it is a string, the string is used.</p> <p>An existing conversation may be used, if available, unless <i>new-conversation-p</i> is true, in which case a new conversation is always created.</p> <p>If a new conversation is created, it is disconnected after <i>body</i> has executed as an implicit program.</p> |                        |

If a conversation cannot be established, the result returned by the function depends on the value of *errorp*. If *errorp* is `t` (the default value), then LispWorks signals an error. If *errorp* is `nil`, the body is not executed, and `nil` is returned.

## The DDE server interface

This chapter describes the Dynamic Data Exchange (DDE) server interface which is available in the `WIN32` package. You should use this chapter in conjunction with Chapter 18, “Dynamic Data Exchange”.

The `WIN32` package also includes functions for accessing miscellaneous Microsoft Windows functionality, the registry API, and the DDE client interface. These are documented in separate chapters in this manual.

**Note:** the `WIN32` package is not a supported implementation of the Win32 API. You should not use symbols in the `WIN32` package unless they are documented in this manual. Instead, define your own interfaces to Windows functions as you need - see the *LispWorks Foreign Language Interface User Guide and Reference Manual* for details.

**Note:** this chapter applies only to LispWorks for Windows, and not the UNIX, Linux, x86/x64 Solaris, FreeBSD or Mac OS X platforms.

| Description | <p>The generic function <code>dde-server-poke</code> is called in response to a poke transaction. A method specializing on the classes of <code>server</code> and <code>topic</code> should poke the data given by <code>data</code> into the item specified by <code>item</code>.</p> <p>The keyword <code>format</code> indicates the format in which the item is being requested. By default, only text transfers are supported (and the <code>format</code> argument will have the value <code>:text</code>).</p> <p>The set of supported formats may be extended in future releases, so applications should always check the value of the <code>format</code> parameter and reject transactions which use formats not supported by the application.</p> <p>If the poke transaction is successful, non-nil should be returned, and <code>nil</code> should be returned for failure.</p> |                  |

| Description | <p>The generic function <code>dde-server-request</code> is called in response to a request transaction. A method specializing on the classes of <code>server</code> and <code>topic</code> should return the data in <code>item</code>.<br/><br/>The expected format of the data is given by <code>format</code>, which defaults to <code>:text</code>. The set of supported formats may be extended in future releases, so applications should always check the value of the <code>format</code> parameter and reject transactions which use formats not supported by the application.<br/><br/>If the request fails, <code>nii</code> should be returned.</p> |                    |

| Values      | <i>topic</i>                                                                                                                                                                                                                                                                                                                                                                                                                | A topic.  |
| Description | The generic function <code>dde-server-topic</code> is called whenever a client attempts to make a connection to the server. The argument <i>topic-name</i> is a string identifying a topic. If the server recognizes the topic, a method specializing on the server should return an instance of one of the server's topic classes. If the server does not recognize the topic, the method should return <code>nil</code> . |           |

| Values      | <i>topic-list</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | A list of strings. |
| Description | The generic function <code>dde-server-topics</code> returns a list of the available general topics on a given server. A suitable method specializing on the server class should be defined. Dispatching topics (see <code>define-dde-dispatch-topic</code> ) should not be returned, as they are handled automatically by LispWorks. If you do not provide a <code>dde-server-topics</code> method, the default method returns <code>:unknown</code> , which prevents the DDE server from responding to the topics request. |                    |

Generally only one canonical name should be returned for each topic, even though the server may recognize several alternative forms of name for a topic. For example, if an application implements a topic for each open file, the topics `foo`, `foo.doc` and `c:\foo.doc` may all be acceptable strings for referring to the same topic; however `dde-server-topics` should return each topic once only.

The application must also provide a method on the `dde-server-topic` generic function.

## **dde-system-topic** *Class*

Summary      A built-in topic class for the `:system` topic.

Package      `win32`

Superclasses    `dde-topic`

Description      The class `dde-system-topic` is a built-in topic class for the `:system` topic.  
  
See “The system topic” on page 221 for details of the items implemented by this topic.

| Subclasses   | <code>dde-system-topic</code>                                                                                                                                                                                                                                                                                                         |
| Description  | The class <code>dde-topic</code> is the superclass of all topic objects. You can define subclasses using <code>defclass</code> and return instances of them by defining a method for the <code>dde-server-topic</code> generic function. This allows you to create topics with arbitrary internal state that can be accessed via DDE. |
| Examples     | See <code>examples\dde\server-dispatching.lisp</code>                                                                                                                                                                                                                                                                                 |

## **define-dde-dispatch-topic** *Macro*

Summary      Defines a dispatch topic.

Package      **win32**

Signature      **define-dde-dispatch-topic name &key server topic-name => name**

Arguments      *name*      A symbol.

*server*      A server class.

*topic-name*      A string.

Values      *name*      A symbol.

Description      The macro **define-dde-dispatch-topic** defines a dispatching topic. A dispatching topic is a topic which has a fixed name and always exists. Dispatching topics provide dispatching capabilities, whereby appropriate application-supplied code is executed for each supported transaction. Note that the server implementation also provides some dispatching capabilities.

The name of the dispatching topic object is specified by *name*.

The topic is identified by the string *topic-name*.

The class of the server to attach the topic to is given by *server*.

The macro **define-dde-dispatch-topic** returns the name of the dispatching topic, *name*.

Use **define-dde-server-function** with the :topic option to define items for a dispatch topic.

|          |                                                                                                                                                                                |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example  | <pre>(define-dde-dispatch-topic topic1 :server demo-server)  (define-dde-server-function (item1 :topic topic1)     :request     ()     ..handle topic1.item1 request...)</pre> |

|             | <code>slot-specs</code>                                                                                                                                                                                                                                                                                                                              | The specifications for the class' slots. |
|             | <code>options</code>                                                                                                                                                                                                                                                                                                                                 | A keyword option.                        |
| Values      | <code>class-name</code>                                                                                                                                                                                                                                                                                                                              | A class name.                            |
| Description | <p>The macro <code>define-dde-server</code> defines a class for a Lisp DDE server. The class inherits from <code>dde-server</code>.</p> <p>The long form of the macro is similar to <code>defclass</code>, but with one extra option, <code>:service</code>, which is used to specify the service name string to which this server will respond.</p> |                                          |

The short form is provided to handle the common simple case; *class-name* is the name of the Lisp class to be defined, and *service-name* is the service name string to which this server will respond.

- Example      The first example uses the short version of `define-dde-server` to define a class, called `lisp-server`, which has the service name “LISP”.

```
(define-dde-server lisp-server "LISP")
```

The second example shows how to use the long form of the macro to define the same class, and illustrates the use of the *superclasses* and *options* arguments.

```
(define-dde-server lisp-server (dde-server)
 ())
 (:service "LISP"))
```

## define-dde-server-function *Macro*

- Summary      Defines a server function that is called when a specific transaction occurs.

- Package      `win32`

- Signature      `define-dde-server-function name-and-options transaction  
(binding*) form* => name`  
  
`name-and-options ::= name | (name [[option]])`  
  
`transaction ::= :request | :poke | :execute`  
  
`option ::= :server server | :topic-class topic-class | :topic  
topic | :item item | :format format | :command command |  
:result-type result-type | :advisep advisep`

```

binding ::= var-binding | execute-arg-binding

var-binding ::= (var :server) | (var :topic) | (var :data
[data-type]) | (var :format)

execute-arg-binding ::= var | (var type-spec)

```

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                   |

|             | <i>form</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A Lisp form.                      |
| Values      | <i>name</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A symbol.                         |
| Description | <p>The macro <b>define-dde-server-function</b> is used to define a server function, called <i>name</i>, which is called when a specific transaction occurs. The defined function may either be attached to a server class (using the dispatching capabilities built into the server implementation) or to a named dispatch topic.</p> <ul style="list-style-type: none"> <li>• To attach the definition to a server, <b>:server</b> should be used to specify the server class. <b>:topic-class</b> may be used to specify the topic-class for which this definition</li> </ul> |                                   |

should be used. It can be a symbol which names a `topic-class`, or `t` (meaning All topics, this is the default for execute transactions), or `:system` (The System topic), or `:non-system` (any topic except the System topic). In the case of execute transactions only, `:topic-class` defaults to `t`; in all other cases, it must be specified. Typically, execute transactions ignore the topic of the conversation. Alternatively, you may choose to only support execute transactions in the system topic.

- A server function may instead be attached to a particular instance of `dde-dispatch-topic`, previously defined by `define-dde-dispatch-topic`. This is the main use of dispatching topics. In this case `:topic` should be provided with a symbol that names a dispatching topic. The function is installed on that topic, and only applies to that topic.

In the case of a request or poke transaction, `item` is a string defining the item name for which this definition should be invoked. It defaults to the capitalized print-name of `name`, with hyphens removed.

For request transactions, the `:format` option is used to specify the format understood. It defaults to `:text`. It can be specified as `:all`, in which case the `:format` binding may be used to determine the actual format requested (see below).

In the case of an execute transaction, `command` is a string specifying the name of the command for which this definition should be invoked. It defaults to the capitalized print-name of `name`, with hyphens removed.

The `execute-arg-bindings` are only used with execute transactions. They specify the arguments expected. `type-spec` should be one of `t`, `string`, `number`, `integer` or `float`. If not specified, `t` is assumed.

The `var-bindings` may appear anywhere in the binding list, and in any order. Binding variables to `:server` and `:topic` is

useful with all transaction types. A `:server` binding causes the variable to be bound to the server object, whereas a `:topic` binding causes the variable to be bound to the topic object. This allows the server and/or the topic to be referred to in the body of the function.

A `:format` binding can only be used with request and poke transactions, where an *option* of `:format :all` has been specified. It causes the variable specified by `var` to be bound to the format of data requested or supplied. The body of the defined function should fail the transaction if it does not support the requested format.

A `:data` binding can only be used with poke transactions. It binds a variable to the data to be poked. For text transfers, the data variable is normally bound to a string. However, if `datatype` is specified as `:string-list`, the data in the transaction is interpreted as a tab-separated list of strings, and the data variable is bound to a list of strings.

For execute and poke transactions, the body of the defined function is expected to return `t` for success and `nil` for failure.

For request transactions, the body of the defined function is normally expected to return a result value, or `nil` for failure.

The `result-type` option may only be specified for request transactions. If it is specified as `:string-list`, then for text requests the body is expected to return a list of strings, which are used to create a tab-separated list to be returned to the client.

Sometimes, it may be necessary to support returning `nil` to mean the empty list, rather than failure. In this case, the `result-type` can be specified as `(:string-list t)`. The body is then expected to return two values: a list of strings, and a flag indicating success.

In the case of execute transactions, the command name and arguments are unmarshalled by the default argument

unmarshalling. This is compatible with the default argument unmarshalling described under `dde-execute-command`. The execute string is expected to be of the following syntax:

```
[command1(arg1,arg2,...)] [command2(arg1,arg2,...)] ...]
```

Note that multiple commands may be packed into a single execute transaction. However, `dde-execute-command` does not currently generate such strings.

## **start-dde-server** *Function*

Summary      Creates and starts an instance of a DDE server.

Package      `win32`

Signature      `start-dde-server name => server`

Arguments      `name`      A DDE server class

Values      `server`      A server object

Description      The function `start-dde-server` creates an instance of a server of the class specified by `name` which then starts accepting transactions. If successful the function returns the server, otherwise `nil` is returned.

You need to call `start-dde-server` in a thread that will process Windows messages. This can either be done by using `capi:execute-with-interface` to run it in the thread of an application's main window (if there is one) or by running it in a dedicated thread as in the example. DDE callbacks will happen in this thread.

**Example**

```
(mp:process-run-function
 "DDE Server"
 ()
 #'(lambda ()
 (win32:start-dde-server 'lispworks-dde-server)
 (loop
 (mp:wait-processing-events
 nil
 :wait-reason "DDE Request Loop"))))
```

## Dynamic library C functions

This chapter describes the C functions available in a LispWorks dynamic library, that is a library created by passing *dll-exports* or *dll-added-files* to `save-image` or `deliver`.

For an overview of this functionality with examples of use, see Chapter 13, “LispWorks as a dynamic library”.

**Note:** this chapter applies only to 32-bit LispWorks on Microsoft Windows, Intel Macintosh, Linux, x86/x64 Solaris and FreeBSD, and 64-bit LispWorks on Windows, Intel Macintosh, Linux and x86/x64 Solaris.

| InitLispWorks | C function                                                                                                                                                                     |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | Provides control over the initialization of a LispWorks dynamic library.                                                                                                       |
| Signature     | On Windows:<br><br><code>int __stdcall InitLispWorks (int MilliTimeOut, void *BaseAddress, size_t ReserveSize)</code><br><br>On Linux, Macintosh, x86/x64 Solaris and FreeBSD: |

```
int InitLispWorks (int MilliTimeOut, void *BaseAddress,
size_t ReserveSize)
```

Description The C function `InitLispWorks` allows you to relocate a LispWorks dynamic library if this is necessary, and offers control of the initialization process.

A LispWorks dynamic library is automatically initialized by any call to its exported symbols, so in most cases there is no need to call `InitLispWorks`. It is however necessary when you need to relocate LispWorks or when you need finer control over the initialization process.

For more information about relocating a LispWorks dynamic library, see “Startup relocation” on page 314)

*MilliTimeOut* specifies the time in milliseconds to wait for LispWorks to finish initializing before returning. `InitLispWorks` checks whether the library was initialized and if not initiates initialization. It then waits at most *MilliTimeOut* milliseconds before returning.

*BaseAddress* specifies the base address for relocation. Can be 0.

*ReserveSize* specifies the reserve size for relocation. Can be 0.

*BaseAddress* and *ReserveSize* are interpreted as described in “Startup relocation” on page 314.

Non-negative return values indicate success:

1           LispWorks was already initialized or in the process of initializing, and finished initializing by the time `InitLispWorks` returned.

0           `InitLispWorks` initialized LispWorks and the initialization finished successfully.

Values in the inclusive range [-1, -99] indicate a timeout:

-1           `InitLispWorks` started initialization and timed out before LispWorks finished mapping itself from the file.

- 2 LispWorks already started initialization, and `InitLispWorks` timed out before LispWorks finished mapping itself from the file.
- 3 `InitLispWorks` started initialization and timed out after LispWorks mapped itself from the file, but before the initialization was complete.
- 4 LispWorks already started initialization, and `InitLispWorks` timed out before after LispWorks mapped itself from the file, but before the initialization was complete.

After `InitLispWorks` times out, the state of LispWorks can be queried by `LispWorksState`.

Lower values indicate failure, as follows:

- 1000 Failure to start a thread to do the initialization.
- 1401 The file seems to be corrupted.
- 1402 Failure to map into memory.
- 1403 Failure to read the LispWorks header from the file.
- 1406 Bad base address.

Additionally, a value *value* in the inclusive range [-1400, -1001] on Linux, Macintosh, FreeBSD and x86/x64 Solaris platforms indicates an error in a system call. Calculate the errno number by -1001 - *value*.

**Note:** If LispWorks is already initialized or in the process of being initialized, `InitLispWorks` does not initiate the process of initialization. Therefore the arguments to `InitLispWorks` have no effect if LispWorks was already initialized when it is called. On Microsoft Windows, the default behavior is to initialize a LispWorks dynamic library automatically during loading, so this needs to be disabled to use

**InitLispWorks** effectively. Disable automatic initialization of a library as described for **deliver** and **save-image**.

**Note:** Once **QuitLispWorks** has returned 0, LispWorks can be initialized again. It is possible to quit and restart Lisp-Works several times, at the same address or at a different address.

**Note:** On Linux, Macintosh, FreeBSD and x86/x64 Solaris you can create wrappers to the C functions described in this chapter from your application by writing them in C and adding them to the dynamic library using *dll-added-files* in **deliver** and **save-image**. Such wrappers can be used to add calls to **InitLispWorks** before actually calling into Lisp.

**InitLispWorks** is defined in each LispWorks dynamic library. For information about creating a LispWorks dynamic library, see **deliver** and **save-image**. For an overview of LispWorks as a dynamic library, see Chapter 13, “*LispWorks as a dynamic library*”.

## LispWorksDlsym

### *C function*

Summary      Returns the address of a foreign callable.

Signature      On Windows:

```
void __stdcall *LispWorksDlsym (const char * name)
```

On Linux, Macintosh, FreeBSD and x86/x64 Solaris:

```
void *LispWorksDlsym (const char * name)
```

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The C function <code>LispWorksDlsym</code> returns the address of a foreign callable <i>name</i> which is defined in Lisp using <code>fli:define-foreign-callable</code>.</p> <p><code>LispWorkDlsym</code> first checks if the LispWorks dynamic library finished initializing, and if not uses <code>InitLispWorks</code> to initialize it (with <i>MilliTimeOut</i> 200). If this fails <code>LispWorkDlsym</code> returns NULL. When the LispWorks dynamic library is initialized, <code>LispWorksDlsym</code> returns the address of <i>name</i>, or NULL if it is not defined.</p> <p><code>LispWorksDlsym</code> is defined in each LispWorks dynamic library. For information about creating a LispWorks dynamic library, see <code>deliver</code> and <code>save-image</code>. For an overview of LispWorks as a dynamic library, see Chapter 13, “LispWorks as a dynamic library”.</p> |

## QuitLispWorks

*C function*

Summary      Allows a LispWorks dynamic library to be unloaded.

Signature      On Windows:

```
int __stdcall QuitLispWorks(int Force, int MilliTimeOut)
```

On Linux, Macintosh, FreeBSD and x86/x64 Solaris:

```
int QuitLispWorks(int Force, int MilliTimeOut)
```

Description      The C function `QuitLispWorks` allows a LispWorks dynamic library to be unloaded. You should make a LispWorks dynamic library 'quit' by calling `QuitLispWorks` before unloading the library. This call causes LispWorks to cleanup everything it uses, in particular the memory and threads.

In general, `QuitLispWorks` should be called only when the LispWorks dynamic library is idle. That is, when there is no callback into the library that has not returned, and there are no processes that has started by a callback. All callbacks should return, and any processes should be killed before calling `QuitLispWorks`.

*Force* should be 0 or 1. It specifies whether to force quitting even if LispWorks is still executing something.

*MilliTimeOut* specifies how long to wait for LispWorks to complete the cleanup.

If LispWorks is idle, `QuitLispWorks` signals it to quit, and waits *MilliTimeOut* milliseconds for it to finish the cleanup. If LispWorks finished cleanup, `QuitLispWorks` return 0 (SUCCESS). If the cleanup is not finished it returns -2 (TIMEOUT).

If LispWorks is not idle, that is there are still some active callbacks or there are processes that have started by a callback (even if they are inside `process-wait`), `QuitLispWorks` checks the value of *Force*. If *Force* is 0, `QuitLispWorks` returns -1 (NOT\_IDLE). If *Force* is 1, `QuitLispWorks` signals it to quit and behaves as if LispWorks is idle, described above.

`QuitLispWorks` can be called repeatedly to check if Lisp-Works finished the cleanup.

When `QuitLispWorks` returns NOT\_IDLE, it has done nothing, and the LispWorks dynamic library can be used for further callbacks. Once `QuitLispWorks` returns any other value, callbacks into the dynamic library will result in undefined behavior.

Once `QuitLispWorks` returns SUCCESS, it is safe to unload the dynamic library. Unloading it before `QuitLispWorks` returns SUCCESS gives undefined results.

Once `QuitLispWorks` returns SUCCESS, LispWorks can be initialized again. Calling any exported function (supplied to `save-image` or `deliver` in *dll-exports*) or any of `InitLispWorks`, `SimpleInitLispWorks` and `LispWorksDlsym` will cause LispWorks to initialize again.

**Note:** On Linux, Macintosh, FreeBSD and x86/x64 Solaris it is possible to add calls to `QuitLispWorks` at the right places via *dll-added-files*.

**Note:** A possible reason for failure to finish the cleanup is that a LispWorks process is stuck inside a foreign call. Dynamic library applications that need to be unloaded should be careful to ensure that they do not get stuck in a foreign function call.

`QuitLispWorks` is defined in each LispWorks dynamic library. For information about creating a LispWorks dynamic library, see `deliver` and `save-image`. For an overview of LispWorks as a dynamic library, see Chapter 13, “LispWorks as a dynamic library”.
