| Arguments                       | <p><i>stream</i> Stream to be bound to the fasl file to be created.</p> <p><i>pathname</i> Name of the fasl file to be created.</p> <p><i>body</i> Forms, some of which may be dumped.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Values                          | Returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description                     | <p><code>with-output-to-fasl-file</code> is used in conjunction with <code>dump-form</code>. The <i>body</i> forms are executed, and during the execution, <code>dump-form</code> may be called to dump selected forms. Dumped forms are evaluated if the file <i>pathname</i> is later loaded by <code>load-data-file</code>.</p> <p>To be able to load the output file, it must have a file type that LispWorks recognizes as a binary file. You can do it by:</p> <ul style="list-style-type: none"> <li>• using the default binary file type, either by using the value of <code>*binary-file-type*</code> as in the example below, or <code>compile-file-pathname</code>.</li> <li>• using another file type, which you add to <code>*binary-file-types*</code>.</li> </ul> <p>If the file <i>pathname</i> already exists, it is superseded.</p> <p>A fasl file created using <code>with-output-to-fasl-file</code> must be loaded only by <code>load-data-file</code>, and not by <code>load</code>.</p> |

**Example**

```
CL-USER 12 > (with-output-to-fasl-file (s
 "/tmp/foo.fasl")
 (dump-form '(print 'hello) s))
NIL

CL-USER 13 > (let ((sys:*binary-file-type* "fasl"))
 (sys:load-data-file "/tmp/foo.fasl"))
; Loading fasl file "/tmp/foo.fasl"

HELLO
#P"/tmp/foo.fasl"
```

## The LINK-LOAD Package

This chapter describes the symbols in the `LINK-LOAD` package.

**Note:** this chapter applies only to LispWorks for UNIX only (not LispWorks for Linux, FreeBSD, or x86/x64 Solaris).

|             |                                                                 | <i>Function</i>                                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>link-load</code>                                          |                                                                                                                                                                                                                                                                                                                   |
| Signature   | <code>break-on-unresolved-functions &amp;optional stream</code> |                                                                                                                                                                                                                                                                                                                   |
| Arguments   | <code>stream</code>                                             | An output stream for message reporting. If set to <code>nil</code> , then no output will be produced. By default this is <code>t</code> .                                                                                                                                                                         |
| Description |                                                                 | The <code>break-on-unresolved-functions</code> function produces break-on-entry code for all currently undefined but referenced (that is, unresolved) foreign symbols, so that if an undefined foreign function is called from within the foreign code, a Lisp error will occur. Break-on-entry code will also be |

produced for any new unresolved symbols loaded later in your Lisp session.

The special variable `foreign:*break-on-unresolved-functions*` will, when set to non-nil, produce break-on-entry code for all new unresolved symbols that are loaded, but won't do so for symbols already loaded. By default this variable is set to nil.

## **foreign-symbol-address** *Function*

Package [link-load](#)

Signature `foreign-symbol-address name &key errorp functionp => result`

Arguments `name` The name of a foreign symbol.  
`errorp` A boolean.  
`functionp` A boolean.

Values `result` The address of `name` or `nil`.

Description The `foreign-symbol-address` function is used to find out whether a foreign symbol is defined, by looking for it in the foreign-symbol table. If its associated object code has been loaded into the image, its address is returned. Otherwise `nil` is returned, unless `errorp` is `nil`.

The `errorp` keyword defines the behavior of the function when a symbol has not been defined. If it is non-nil (which is the default value), then an error will be signalled. If it is `nil`, no error will be reported, and the function will return `nil`.

The `functionp` keyword is used to specify the kind of symbol sought. If it is `t`, `foreign-symbol-address` will assume that

*name* is the name of a function. If it is `nil` it will assume that *name* is the name of a variable. The default value is `t`.

Example      `(foreign-symbol-address 'chmod)`

See also      `get-foreign-symbol`

## **get-foreign-symbol** *Function*

Package      `link-load`

Signature      `get-foreign-symbol name &optional force => result`

Arguments      *name*      A symbol or string.

*force*      A keyword.

Values      *result*      A foreign symbol.

Description      This function gets a foreign symbol or it may be used to explicitly register an undefined symbol.

*name* is a symbol or string to look up or to create as a foreign symbol. If it is a symbol, the symbol looked for is that which the function `lisp-name-to-foreign-name` would produce. If *name* is a string, it is taken literally

If supplied and the symbol is not already defined as a foreign symbol, *force* forces it to be an undefined foreign symbol. This provides a reference to the symbol so that a subsequent call to `read-foreign-modules` will attempt to resolve it

Example      `(get-foreign-symbol 'my-func-not-yet-loaded t)`

Notes      It is not usually necessary to use this function. In order to examine whether a foreign symbol is defined, use `foreign-symbol-address`. The act of defining a foreign function

using `fli:define-foreign-function` makes the symbol undefined, so the use of force is not usually needed.

|             |                                                                                                                                                                                                                                                                                                                                                                 | <i>Function</i> |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Package     | <code>link-load</code>                                                                                                                                                                                                                                                                                                                                          |                 |
| Signature   | <code>lisp-name-to-foreign-name name &amp;key language</code>                                                                                                                                                                                                                                                                                                   |                 |
| Arguments   | <p><code>name</code> A symbol representing a Lisp name. (Strings are passed unchanged through the function.)</p> <p><code>language</code> If :c then an equivalent ‘C’ name is produced. :FORTRAN is an alternative.</p>                                                                                                                                        |                 |
| Description | This function provides an equivalent foreign name for a Lisp name, depending on the keyword language.                                                                                                                                                                                                                                                           |                 |
| Values      | A string is returned which is a foreign equivalent of the Lisp name supplied. If name is a string, the function returns the string unchanged. If language is a symbol, the ‘C’ version replaces occurrences of ‘-’ with ‘_’ and adds a leading underscore. The Fortran version replaces occurrences of ‘-’ with ‘_’ and adds a leading and trailing underscore. |                 |
| Example     | <code>(lisp-name-to-foreign-name 'lisp-name-with-hyphens)<br/> "lisp_name_with_hyphens"</code>                                                                                                                                                                                                                                                                  |                 |
| See also    | <code>get-foreign-symbol</code>                                                                                                                                                                                                                                                                                                                                 |                 |

|                      | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Description          | <p>The <code>read-foreign-modules</code> function reads object files of various formats into the Lisp image. Unresolved references are resolved wherever possible and the names of the foreign functions are made available to the Lisp for direct calling from the Lisp if desired. With no argument, <code>read-foreign-modules</code> scans the default libraries looking for definitions of referenced but undefined symbols.</p> <p>The <code>module-names</code> argument is a sequence of items representing object files to be loaded. The items may be of type string or pathname, and will be used to look up a corresponding file in the file system. The only exception is if an item is a string beginning “-1” in which case the rest of the string is used to look up a library file using format strings constructed from the values of the variable <code>*default-library-name-search-paths*</code>, the environment variable <code>LD_LIBRARY_PATH</code> and the variable <code>*default-library-names*</code>. Object files of various formats and library files can be handled by <code>read-foreign-modules</code>.</p> |
| Example              | <pre>(read-foreign-modules "/usr/users/clc/projects/head.o"                       "~clc/projects/libs.a"                       "-lw")</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Notes                | The <code>read-foreign-modules</code> function actually adds the <code>module-names</code> to the list of modules in the variable <code>*default-libraries*</code> and then tries to resolve any undefined symbols using this list. The function <code>get-for-</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

`eign-symbol` may be called to explicitly force a symbol onto the undefined list or the act of defining a foreign function (`fli:define-foreign-function`) will do it implicitly.

`read-foreign-modules` may be called at any time during the running of a program and a particular object file may be loaded as often as is necessary.

A warning of any new unresolved references will be printed out after the reading has finished if the flag `*unresolved-messages*` is set to `t` (the default is `nil`). By default messages are printed out about which object modules are being loaded. This may be switched off by setting `*coff-loading-verbose*` to `nil`.

## The LISPWORKS Package

This chapter describes symbols available in the `LISPWORKS` package. This package is used by default. Its symbols are visible in the `CL-USER` package.

Various uses of the symbols documented here are discussed throughout this manual.

|             |                                         | <i>Type</i>                                                                                                                                    |
|-------------|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | The 8 bit string type.                  |                                                                                                                                                |
| Package     | <code>lispworks</code>                  |                                                                                                                                                |
| Signature   | <code>8-bit-string <i>length</i></code> |                                                                                                                                                |
| Arguments   | <code><i>length</i></code>              | The length of the string (or <code>*</code> , meaning any).                                                                                    |
| Description |                                         | The type of strings that can hold simple chars of codes 0...255. This is the string type that is guaranteed to always take 8 bits per element. |

| <b>16-bit-string</b> | <i>Type</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary              | The 16 bit string type.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Package              | <b>lispworks</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Signature            | <b>16-bit-string <i>length</i></b>                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Arguments            | <b><i>length</i></b> The length of the string (or *, meaning any).                                                                                                                                                                                                                                                                                                                                                                                                              |
| Description          | The type of strings that can hold simple chars of codes 0...65533. This is the string type that is guaranteed to always take 16 bits per element.                                                                                                                                                                                                                                                                                                                               |
| <br>                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>append-file</b>   | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Summary              | Appends the contents of a file to another file.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Package              | <b>lispworks</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Signature            | <b>append-file <i>from to</i></b>                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Arguments            | <b><i>from</i></b> A pathname specifier.<br><b><i>to</i></b> A pathname specifier.                                                                                                                                                                                                                                                                                                                                                                                              |
| Description          | The function <b>append-file</b> appends the contents of the file <i>from</i> to another file. The file <i>from</i> must exist.<br><br><b>append-file</b> opens <i>from</i> for input and <i>to</i> for output using <i>if-exists :append</i> (see <b>cl:open</b> in the <i>Common Lisp HyperSpec</i> ) and copies the contents from <i>from</i> to <i>to</i> .<br><br>On any failure <b>append-file</b> signals an error.<br><b>append-file</b> does not return a useful value. |

## **base-character** *Type*

Summary      The base character type.

Package      `lispworks`

Signature      `base-character`

Description      The type of base characters.

`base-character` is a synonym for the Common Lisp type `base-char`.

See also      `base-char-code-limit`

## **base-character-p** *Function*

Summary      Tests if an object is a base character

Package      `lispworks`

Signature      `base-character-p object => bool`

Arguments      `object`                  The object to be tested.

Values      `bool`                  `t` if `object` is a base character; `nil` otherwise.

Description      This is the predicate for base characters.

See also **base-character**

|-------------|-------------------------------------------------------------------------------------------------|--|
| Summary     | Upper bound for character codes in base characters.                                             |  |
| Package     | <b>lispworks</b>                                                                                |  |
| Description | The upper exclusive bound for values of ( <b>char-code</b> <i>char</i> ) among base characters. |  |

## **base-string-p** *Function*

|         |                                      |  |
|---------|--------------------------------------|--|
| Summary | Tests if an object is a base string. |  |
| Package | <b>lispworks</b>                     |  |

|             |                                                   |                                                                   |
|-------------|---------------------------------------------------|-------------------------------------------------------------------|
| Signature   | <b>base-string-p</b> <i>object</i> => <i>bool</i> |                                                                   |
| Arguments   | <i>object</i>                                     | The object to be tested.                                          |
| Values      | <i>bool</i>                                       | <i>t</i> if <i>object</i> is a base string; <i>nil</i> otherwise. |
| Description | This is the predicate for base strings.           |                                                                   |
| See also    | <b>base-string</b>                                |                                                                   |

## \*browser-location\* *Variable*

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Description   | <p>Controls how the online documentation interface and the function <b>open-url</b> find a web browser executable (either Netscape, Firefox, Mozilla or Opera) to use. The value should be <b>nil</b> or a string.</p> <p>If the value is <b>nil</b>, LispWorks attempts to find the browser using the value of the environment variable <b>PATH</b>.</p> <p>If the value is a string, it specifies the directory in which the browser is installed. Typical values are <b>"/usr/bin/"</b> and <b>"/usr/local/bin/"</b>.</p> <p><b>Note:</b> do not omit the trailing slash.</p> <p><b>Note:</b> <b>*browser-location*</b> is used only in the Motif-based IDE.</p> |

| Signature               | <code>call-next-advice args</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Arguments               | <code>args</code> are arguments to be given to the next piece of advice to be called. Any number of arguments may be given in this way, including keyword arguments, and there is no requirement for pieces of around advice to receive the same number of arguments as the original definition expected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Values                  | <code>call-next-advice</code> returns the values produced by the call to the next piece of advice (or to the combination of before and after advice and the original definition).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description             | <code>call-next-advice</code> is the local function used to invoke the next item in the ordering of pieces of advice associated with a function. It can only be called from within the scope of the around advice. Advice may be attached to a function by <code>defadvice</code> and this allows the behavior of a function to be modified. Extra code to be performed before or after the function may be simply added by creating before or after advice for it. Around advice is more powerful and replaces the original definition. All the advice for a function is ordered with the around advice coming first.<br><br>The first piece of around advice receives the arguments to the function and may return any values at all. It has access to the rest of the advice, and to the original definition, by means of <code>call-next-advice</code> . A call to this from within the body of the around advice invokes the next piece of around advice with the arguments given to <code>call-next-advice</code> . The last piece of around advice in the ordering invokes the sequence of before advice, the original definition, and after advice if it calls |

`call-next-advice`. Around advice may contain any number of calls to `call-next-advice`, including no calls.

|          |                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>call-next-advice</code> is an extension to Common Lisp. See Chapter 6, “The Advice Facility” for a broader discussion of <code>advice</code> . |

| Description | <p>The function <code>choose-unicode-string-hash-function</code> return a function which is suitable for use as the <code>hash-function</code> argument to <code>make-hash-table</code>. The function <code>hash-function</code> generates a hash value for a string, ignoring case using specified Unicode comparison rules specified by <code>style</code>.</p> <p>The current implementation only supports one value of <code>style</code>: <code>:simple-case-fold</code></p> <p>Compares each character of the string using Unicode's simple case folding rules.</p> |                 |

| Summary   | The function <code>compile-system</code> compiles all the files in a system necessary to make a consistent set of object files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Arguments | <p><code>system-name</code> A symbol representing the name of the system. The system must have been defined already using the <code>defsystem</code> macro.</p> <p><code>force</code> If <code>t</code> then all the files in the system are compiled regardless. (This argument was formerly called <code>force-p</code>. The old name is currently still accepted for compatibility.)</p> <p><code>simulate</code> If <code>nil</code> or not present then <code>compile-system</code> works silently. Otherwise a plan of the actions which <code>compile-system</code> intends to carry out is printed. What happens next depends on the value of <code>simulate</code>:</p> <ul style="list-style-type: none"> <li><code>t</code> — do nothing.</li> <li><code>:ask</code> — you are asked if you wish the plan to be carried out using <code>y-or-n-p</code>.</li> <li><code>:each</code> — <code>compile-system</code> displays each action in the plan one at a time, and asks you whether you want to carry out this particular action. The answer <code>c</code> executes the rest of the plan without further prompting, returns from <code>compile-system</code> without further processing, and <code>y</code> and <code>n</code> work as expected.</li> </ul> <p><code>:simulate</code> may be abbreviated as <code>:sim</code>.</p> |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>load</i>             | If <i>t</i> then <code>load-system</code> is called after <code>compile-system</code> has finished. If <code>:no</code> then no files are loaded at all. The default is <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>args</i>             | Arguments to be passed directly to the compiler.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>target-directory</i> | This must be a string representing a valid directory. It defaults to the <code>:default-pathname</code> option to <code>defsystem</code> . This is the directory where the object files created are put. If the <i>target-directory</i> is given then dependency information expressed in the system rules is ignored. <code>:target-directory</code> may be abbreviated as <code>:t-dir</code> .                                                                                                                                                                           |
| Values                  | <code>compile-system</code> returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Examples                | <pre>(compile-system 'blackboard :simulate :ask)  (compile-system 'tms :load t)  (compile-system 'packages :load :no                  :target-directory "/usr/users/386i/")</pre>                                                                                                                                                                                                                                                                                                                                                                                           |
| Notes                   | If <i>load</i> is <i>t</i> then <code>load-system</code> is called after the system has been compiled.<br><br>C source files, for example <code>foo.c</code> , can be included in a system (see the use of <code>:default-type</code> and <code>:type</code> in <code>defsystem</code> ). The corresponding object file name is <code>foo.so</code> on Linux, and on Unix it is <code>foon.o</code> where <i>n</i> is a platform-specific integer. On Mac OS X the object file name is <code>foo.dylib</code> and on Windows the object file name is <code>foo.dll</code> . |

| Summary     | Produces a single, concatenated fasl from a <code>defsystem</code> system or systems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Package     | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Signature   | $\text{concatenate-system } \text{output system} \&\text{key force simulate sim}$ $\text{source-only args target-directory t-dir script-p} \Rightarrow \text{result}$ $\text{system} ::= \text{system-name}^*$                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Arguments   | <p><i>output</i>      The name of the required concatenated fasl.</p> <p><i>system-name</i>      The name of a system defined using <code>defsystem</code>.</p> <p><i>simulate</i>      Verbosity conditions, see Description for more detail.</p> <p><i>sim</i>      Same as <i>simulate</i>.</p> <p><i>force</i>      If <i>t</i>, then all files in the system will be concatenated.</p> <p><i>source-only</i>      If <i>t</i>, the source files of the system are concatenated.</p> <p><i>target-directory</i>      The directory to search for the object files.</p> <p><i>t-dir</i>      Same as <i>target-directory</i>.</p> |
| Values      | A list containing the name or names of the concatenated systems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description | <p>This function produces a single, concatenated fasl, <i>output-file</i>, from a list of individual systems (named amongst the <i>args</i>).</p> <p>Since concatenated fasl files may be produced in this way, you do not need to be wary of MS filename conventions if developing sources on UNIX for a Microsoft Windows application. This clearly allows more freedom for naming source</p>                                                                                                                                                                                                                                      |

files. However, *output-file* must, in such cases, be a MS-Windows-compatible filename.

If *simulate* is `nil` or is not present, `concatenate-system` will work silently. Otherwise, a plan of the actions which `concatenate-system` intends to carry out is printed. What happens next depends upon the value of *simulate*:

- If it is `t`, the function does nothing.
- If `:ask`, then the user is asked, using `y-or-n-p`, if the plan should be carried out.
- If it is `:each`, the user is asked at each stage in the plan if the current action should be carried out. The responses `y` and `n` work as normal. If `e` is typed, `concatenate-system` exits without further processing.

If *source-only* is `t`, files will be loaded only if they are sources.

If, when searching *target-directory* for an object file, the file cannot be found, the appropriate source file from the system's default directory will be loaded instead.

| Summary          | Copies the contents of a file to another file.                                                                                                      |             |                       |           |                       |
| Package          | <code>lispworks</code>                                                                                                                              |             |                       |           |                       |
| Signature        | <code>copy-file from to</code>                                                                                                                      |             |                       |           |                       |
| Arguments        | <table border="0"> <tr> <td><i>from</i></td><td>A pathname specifier.</td></tr> <tr> <td><i>to</i></td><td>A pathname specifier.</td></tr> </table> | <i>from</i> | A pathname specifier. | <i>to</i> | A pathname specifier. |
| <i>from</i>      | A pathname specifier.                                                                                                                               |             |                       |           |                       |
| <i>to</i>        | A pathname specifier.                                                                                                                               |             |                       |           |                       |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>copy-file</code> copies the contents of the file <i>from</i> to another file. The file <i>from</i> must exist.</p> <p><code>copy-file</code> opens <i>from</i> for input and <i>to</i> for output using <i>if-exists :supersede</i> (see <code>cl:open</code> in the <i>Common Lisp HyperSpec</i>) and copies the contents from <i>from</i> to <i>to</i>.</p> <p>On any failure <code>copy-file</code> signals an error.</p> <p><code>copy-file</code> does not return a useful value.</p> |
| See also    | <code>append-file</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| current-pathname |                                                                                                                                                                                                                                                                                                                                                                                                                     | Function                                                         |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| Summary          | Computes a pathname relative to the current path.                                                                                                                                                                                                                                                                                                                                                                   |                                                                  |
| Package          | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                              |                                                                  |
| Signature        | <code>current-pathname &amp;optional relative-pathname type =&gt; pathname</code>                                                                                                                                                                                                                                                                                                                                   |                                                                  |
| Arguments        | <i>relative-pathname</i>                                                                                                                                                                                                                                                                                                                                                                                            | A pathname designator.                                           |
|                  | <i>type</i>                                                                                                                                                                                                                                                                                                                                                                                                         | A string or <code>nil</code> . The default is <code>nil</code> . |
| Values           | <i>pathname</i>                                                                                                                                                                                                                                                                                                                                                                                                     | A pathname.                                                      |
| Description      | <p>The function <code>current-pathname</code> is useful for loading other files relative to a file.</p> <p><code>current-pathname</code> computes a pathname from the current operation as follows:</p> <p>When loading a file</p> <p style="padding-left: 40px;">Uses <code>*load-pathname*</code>.</p> <p>When compiling a file</p> <p style="padding-left: 40px;">Uses <code>*compile-file-pathname*</code>.</p> |                                                                  |

When evaluating or compiling an Editor buffer

Uses the pathname of the buffer, if available, otherwise uses the current working directory.

Otherwise

Uses the current working directory.

The pathname computed above is then translated to a physical pathname, and the argument *relative-pathname* is merged with this physical pathname. The `pathname-type` of the result `pathname` is set to `type` if supplied, the `pathname-version` is set to `:newest`, and `pathname` is returned.

A useful value for `type` is `nil`, which can be used to allow `load` to choose between lisp or fasl regardless of the type of the current pathname.

**Notes** `defsystem` uses `current-pathname` with its `:default-host` argument.

**Examples** Suppose you want the file `foo` to load the file `bar`.

While loading the source file `foo.lisp`:

```
(current-pathname "bar")
=>
#P"C:/temp/bar.lisp"
```

While loading the binary file `foo.ofasl`:

```
(current-pathname "bar")
=>
#P"C:/temp/bar.ofasl"
```

To load `bar.lisp` or `bar.ofasl` according to the value of `*load-fasl-or-lisp-file*`, regardless of whether `foo.lisp` or `foo.ofasl` is being loaded, specify `type nil`:

```
(load (current-pathname "bar" nil))
```

## defadvice

Macro

**Summary** Defines a new piece of advice.

## Package **lispworks**

**Signature**      **defadvice** (*dspec name advice-type &key where documentation*)  
                  *lambda-list &body body => nil*

```
dspec ::= fn-name |

 macro-name |

 (method generic-fn-name [(class*)])
```

**advice-type** ::= **:before** | **:after** | **:around**

| Arguments | <i>dspec</i> | Specifies the functional definition to which the piece of advice belongs. There are three forms which this specification may take. The first one above specifies a function by its name; the second one specifies a macro by name; the third specifies a method by the name of its generic function and by a list of classes to specialize the arguments to the method. In the case of a method the list of classes must correspond exactly to the classes of the specialized parameters of an existing method, and the advice is then attached to this method. |
|-----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|-----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

When advice is provided for a macro using `defadvice`, then the function with which the advice is associated is the expansion function for that macro. Thus before and after advice for a macro receive the argu-

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | ments given to the macro expansion function, which are normally the macro call form and an environment.                                                                                                                                                                                                                                                                                                                                              |
| <i>name</i>          | A symbol naming the piece of advice being created. It should of course be unique to the advised function, but does not need to be globally unique.                                                                                                                                                                                                                                                                                                   |
| <i>advice-type</i>   | A keyword specifying the kind of advice wanted.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>where</i>         | Specifies where this advice should be placed in the ordering of pieces of advice for the function. By default a piece of advice is placed at the start of the corresponding section. If this argument is present and is :end then the advice is instead placed at the end of its section. The other permissible value for this argument is :start, which places the advice at the start of its section in the ordering (as in the default behavior). |
| <i>documentation</i> | A string providing documentation on the piece of advice.                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>lambda-list</i>   | A lambda list for the piece of advice. In the case of before and after advice this should be compatible with the lambda list for the original definition, since such advice receives the same arguments as that function.                                                                                                                                                                                                                            |
| <i>body</i>          | The main body of the advice.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Values               | <code>defadvice</code> returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description          | <code>defadvice</code> is the macro used to define a new piece of advice. Advice provides a way to change the behavior of existing functional definitions in the system. In a simple instance advice might be used to carry out some additional actions                                                                                                                                                                                              |

before or after the original definition. More sophisticated uses allow the definition to be replaced by new code that can access the original function repeatedly or as rarely as desired, and that can receive different numbers of arguments and return any values. A function may have any number of pieces of advice attached to it by using `defadvice`.

There are three kinds of advice that may be defined: before, after and around advice. The first two kinds attach auxiliary code to be carried out alongside the original definition (before it for before advice, after it in the case of after advice). Around advice replaces the function altogether; it may define code that never accesses the original definition, that receives different numbers of arguments, and returns different values. All the pieces of advice for a function are ordered. The ordering is important in determining how all the pieces of advice for a function are combined. Around advice always comes first, then before advice, then the original definition, and lastly the after advice.

Conceptually the before advice, the original definition and the after advice are amalgamated into one new construct. If this gets called then each of its components receives the same arguments in turn, and the values returned are those produced by the last piece of after advice to be called in this way (or the original function if there is no after advice). The code associated with before and after advice should not destructively modify its arguments.

If around advice is present then the first piece of around advice is called, instead of the combination involving before and after advice discussed above. It does not have to access any of the other advice, nor the original definition. Its only link to the rest of the advice is by means of a call to `call-next-advice`. It may invoke this as often as it chooses, and by doing so it accesses the next piece of around advice if present, or else it accesses the combination of before and after advice together with the original definition.

Remove advice using `remove-advice` or `delete-advice`.

Notes `defadvice` is an extension to Common Lisp.

`remove-advice`

### **\*default-action-list-sort-time\*** *Variable*

Summary Determines when actions in action lists are sorted.

Package `lispworks`

Signature `*default-action-list-sort-time*`

Initial value `:execute`

Description The variable `*default-action-list-sort-time*` is a keyword that is either `:execute` or `:define-action`, denoting when actions in action-lists are sorted (see `define-action-list` for an explanation of ordering specifiers). Actions are sorted either at time of definition (`:define-action`) or when their action-list is executed (`:execute`). The default sort time is `:execute`.

See also `define-action`  
`define-action-list`

### **\*default-character-element-type\*** *Parameter*

Summary Provides defaults for all character type parameters.

Package `lispworks`

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>This parameter provides defaults for all character type parameters. The legal values are <code>base-char</code>, <code>lw:simple-char</code>, and <code>character</code>. Its value must only be set via a call to <code>set-default-character-element-type</code>.</p> <p>This is intended for efficiency of applications with only 8-bit strings. If your program uses 16-bit strings you should already be aware of these issues, and make some attempt to provide explicit types.</p> <p>When the compiler does type inferencing it behaves as if this variable was bound to <code>character</code>; if you want assumptions about types to be hard-coded into your program, you must supply explicit declarations and type arguments.</p> |

| Signature   | <code>define-action name-or-list action-name data &amp;rest specs =&gt;</code>                                                                                                                                           |                               |
| Arguments   | <code>name-or-list</code>                                                                                                                                                                                                | A list or action list object. |
|             | <code>action-name</code>                                                                                                                                                                                                 | A general lisp object.        |
|             | <code>data</code>                                                                                                                                                                                                        | An object.                    |
|             | <code>specs</code>                                                                                                                                                                                                       | A list.                       |
| Description | The <code>define-action</code> macro adds a new action to the action list specified by <code>name-or-list</code> ; this action will be executed according to the action-list's execution-function (see <code>exe-</code> |                               |

`cute-actions`) when executed. If the action-list specified by `name-or-list` does not exist, then this is handled according to the value of `*handle-missing-action-list*`.

`name-or-list` is evaluated to give either a list UID (to be looked up in the global registry of lists) or an action list object. `action-name` is a UID (general lisp object, to be compared by `equalp`). It uniquely identifies this action within its list (as opposed to among all lists).

`data` specifies an object referring to data relevant to the action.

`specs` is a free-form list of ordering specifiers and extra keywords, used to control more details of how and when this action is executed.

Action-items are normally expected not to be redefined. If an action-item with that action-name already exists in the action-list (that is, one with an identifier `equalp` to the action-name), then the notification and subsequent handling of this attempt is controlled by the values in the list `*handle-existing-action-in-action-list*`. This is to prevent problems due to re-evaluating an action definition inappropriately. Notification and redefine behavior can be overridden by using the `:force` keyword argument. In this case, any required redefinition is performed unconditionally and without notification.

The following keywords are recognized in the `specs` argument:

|                      |                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>:after</code>  | The following element in <code>specs</code> is a UID.<br><code>:after</code> specifies that the action-item being defined must be run after the action-item named. If there is no action-item with a matching name, the restriction is ignored. |
| <code>:before</code> | Like <code>:after</code> , but this action-item must be run before the one specified.                                                                                                                                                           |

`:after` and `:before` can be specified as many times as necessary to describe the ordering constraints of this action-item with respect to its neighbors.

`:once`      Specifies that this action-item should be executed only once; after execution, it is disabled.

`:force`      Specifies that this definition should override any previous definition of this action-item, rather than be subject to the value of `*handle-existing-action-in-action-list*`.

Example      

```
(define-action :network-startup "Reset decnet buffers"
 '(decnet::reset-network-buffers
 net-buffers)
 :after "Reset core network"
 :once))
```

## define-action-list

*Macro*

Summary      Defines a registered action list.

Package      `lispworks`

Signature      `define-action-list uid &key documentation sort-time dummy-actions default-order execution-function =>`

Arguments      `uid`      A Lisp object.

`documentation`      A string.

`sort-time`      One of `:execute` or `:define-action`.

`dummy-actions`      A list.

`default-order`      A list.

`execution-function`      A function.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The <code>define-action-list</code> macro defines an action list.</p> <p><i>uid</i> is a unique identifier, and must be a general Lisp object, to be compared by <code>equalp</code>. It names the list in the global registry of action lists. See <code>make-unregistered-action-list</code> to create unnamed, “unregistered” action-lists. The <i>uid</i> may be quoted, but is not required to be. It is possible, but not recommended, to define an action-list with unique identifier <code>nil</code>. If a registered action-list with the <i>uid</i> already exists (that is, one which returns <code>t</code> when compared with <code>equalp</code>), then notification and subsequent handling is controlled by the value of the <code>*handle-existing-action-list*</code> variable.</p> <p>The <i>documentation</i> string allows you to provide documentation for the action list.</p> <p><i>sort-time</i> is a keyword specifying when added actions are sorted for the given list — either <code>:execute</code> or <code>:define-action</code> (see <code>*default-action-list-sort-time*</code>).</p> <p><i>dummy-actions</i> is a list of action-names that specify placeholder actions; they cannot be executed and are constrained to the order specified in this list, for example</p> <pre>'(:beginning :middle :end)</pre> <p><i>default-order</i> specifies default ordering constraints for subsequently defined action-items where no explicit ordering constraints are specified. An example is</p> <pre>'(:after beginning :before :end)</pre> <p><i>execution-function</i> specifies a function that you define. It must accept arguments of the form:</p> <pre>(the-action-list other-args-list &amp;rest keyword-value-pairs)</pre> <p>where the two required arguments are the action-list and a list of additional arguments passed to <code>execute-actions</code>, respectively. The remaining arguments are any number of keyword-value pairs that may be specified in the call to <code>execute-actions</code>. If no execution function is specified, then</p> |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

the default execution function will be used to execute the action-list.

See the manual entries for `with-action-list-mapping` and `with-action-item-error-handling` for examples of execution-functions.

To add an action to an action list you have defined, use `define-action`.

|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | <code>defsystem</code> is used to define systems for use with the Lisp-Works system tools. A system is a collection of files and other systems that, together with rules expressing the interdependencies of those files and subsystems, make a complete program. The LispWorks system tools support the development and maintenance of large programs. Find a full description at “Common Defsystem and ASDF” on page 197. |
| Package   | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                      |
| Signature | <code>defsystem system-name options &amp;key members rules =&gt; system</code>                                                                                                                                                                                                                                                                                                                                              |
| Arguments | <p><code>system-name</code>      The name of the system to be made.<br/><code>options</code> are expressed as a list of keyword argument pairs. The following keywords are recognized:</p>                                                                                                                                                                                                                                  |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>:package</b>          | The default package that files are compiled and loaded in. If not specified, this defaults to the value of <b>*package*</b> at macroexpansion time.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>:default-pathname</b> | Used to compute a default pathname in which to find files. <b>defsystem</b> uses <b>current-pathname</b> to compute the pathname. <b>defsystem</b> checks that all the files given as members actually exist.                                                                                                                                                                                                                                                                                                                                                   |
| <b>:default-host</b>     | The root pathname of a system is defined to be the <b>:default-host</b> if it is given. Otherwise, it is taken to be the directory containing the defsystem file.<br><br>Absolute pathnames are interpreted literally, and relative pathnames are taken relative to the root pathname.                                                                                                                                                                                                                                                                          |
| <b>:default-type</b>     | This is the default type of the members of the system. This may be <b>:lisp-file</b> , <b>:lsp-file</b> , <b>:c-file</b> , or <b>:system</b> .<br><br>The corba module adds <b>:idl-file</b> , <b>:idl-client-definition</b> , <b>:idl-client-definition-only</b> , <b>:idl-server-definition</b> and <b>:idl-server-definition-only</b> .<br><br>The com module adds the type <b>:midl-file</b> and the automation module adds <b>:midl-type-library-file</b> .<br><br>The default is <b>:lisp-file</b> , which means files with file type (extension) "lisp". |
| <b>:documentation</b>    | This is a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>:object-pathname</b>  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

A string or pathname specifying a directory where object files are written.

**Note:** This option will not work if the names in *members* represent absolute pathnames.

**:optimize** A declaration specifying default compilation qualities within the scope of `compile-system`. These settings override the current global setting. They can be overridden per member by the `:optimize` option (for subsystems) or `proclaim` (in files). The `:optimize defsystem` option accepts the same optimize qualities as `proclaim` and which are fully described in “Compiler control” on page 88. See below for examples.

*members* is a list defining the members of the system. Elements of the list may be a string *name* representing the name of the physical file or system referred to. Elements of the list may also be a symbol, which is interpreted as its symbol name.

Elements of the *members* list can also be a list of the form `(name {keyword value}*)` where *name* is once again a string or a symbol naming a file or system.

The members of *system-name* must have unique names, as compared by `equalp`. For example, if *members* contains “`foo`” then there cannot be another member (either a file or a system) named “`foo`”, “`FOO`” or `foo`.

The possible keywords and their values are:

**:type** The type of this member. Allowed values are as for `:default-type`. If not specified it defaults to the value of `:default-type` given as an *option*.

**:root-module** If `nil` then this member is not loaded unless its loading is specifically requested as a result of a dependency on another module

|                               |                                                                                                      |
|-------------------------------|------------------------------------------------------------------------------------------------------|
| <b>:source-only</b>           | Only the source file for this member is ever loaded                                                  |
| <b>:load-only</b>             | The member is never compiled by <b>defsys-tem</b> , objects are loaded in preference to source files |
| <b>:load-for-compile-only</b> |                                                                                                      |
|                               | The member is only loaded as necessary during compilation and is never loaded independently          |
| <b>:features</b>              | The member is only considered during planning if the feature expression is true.                     |
| <b>:package</b>               | A default package for the member.                                                                    |

On Windows, the automation module adds the keyword

**:com** for a member with type **:midl-type-library-file**.

Then a member of the form

```
("mso97.tlb" :type :midl-type-library-file :com nil)
```

can be specified when you use only Automation client code, reducing the memory used.

*rules* is a list of rules of the following format :

```
({:in-order-to} action {:all | ({ member-name }*)}
 (:caused-by {(action {:previous | {member-name }* }) }*)
 (:requires {(action {:previous | { member-name }* }) }*))
```

The keyword **:all** refers to all the members of the system. It provides a shorthand for specifying that a rule should apply to all the system's members. The keyword **:previous** refers to all the members of the system that are before the member in the list of members. This makes it easy, for example, to specify that in order to compile a file in a system, all the members that come before it must be loaded.

There are more details about the rules in “DEFSYSTEM rules” on page 200.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values   | The name of the system is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Examples | <pre>(defsystem defsys-macros   (:default-pathname "/usr/users/james/scm/defsys/"   :default-type :lisp-file   :package defsystem)   :members ("new-macros"             "scm-timemacros"))  (defsystem clos-sys   (:default-pathname "/usr/users/clc/defsys/"   :default-type :lisp-file   :package defsystem)   :members   ((("defsys-macros" :type :system :root-module nil)     "class"     "time-methods"     ("scm-pathname" :source-only t)     "execute-plan"     "file-types"     "make-system"     "conv-defsys"))   :rules   (((:in-order-to :compile ("class" "time-methods")       (:caused-by (:compile "defsys-macros"))       (:requires         (:load "defsys-macros")))     (:in-order-to :compile       ("time-methods" "execute-plan")       (:requires (:load "class")))))  (defsystem dataworks-demo   (:default-type :system)   :members (     "db-class"     "planar"     "dataworks-dep"     "dataworks-interface-tk"     "dataworks-interface-tools"     "drugs-demo"     ("gen-demo" :type :lisp-file)     ("load-icon" :type :lisp-file :source-only t)     )   :rules ((:in-order-to :compile :all     (:requires (:load :previous)))))</pre> |

This last example illustrates the use of `:optimize`.

```
(defsystem foo (:optimize ((speed 3) (space 3)
 (safety 0)))
 :members ("bar"
 "baz")
 :rules ((:compile :all
 (:requires (:load :previous)))))
```

| Description             | <p>The function <b>delete-directory</b> attempts to delete the directory <i>directory</i>. It returns <b>t</b> on success, and on failure either returns <b>nil</b> or signals an error.</p> <p><i>error</i> determines what happens when <b>delete-directory</b> fails. When <i>error</i> is <b>nil</b> (the default), if <i>directory</i> does not exist <b>delete-directory</b> returns <b>nil</b>, otherwise any failure causes an error to be signaled. If <i>error</i> is <b>:no-error</b>, <b>delete-directory</b> returns <b>nil</b> on any failure. If <i>error</i> is <b>:error</b>, any failure causes an error to be signaled.</p> <p>Typical reasons for failures in <b>delete-directory</b> are that <i>directory</i> is not empty, or that the user does not have the right permissions.</p> |                         |                        |                     |                                                  |

|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>deliver</code> is the main interface to the LispWorks delivery tools. You use it to create LispWorks executable applications and dynamic libraries.</p> <p>For more information about Delivery including a detailed description of <code>deliver</code>, see the <i>LispWorks Delivery User Guide</i>.</p> <p>For information about invoking <code>deliver</code> using the IDE, see "The Application Builder" in the <i>LispWorks IDE User Guide</i>.</p> |
| Notes       | <code>deliver</code> checks that <code>load-all-patches</code> has been called. If it is called before <code>load-all-patches</code> in a session then an error is signalled.                                                                                                                                                                                                                                                                                                    |

|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary                  | Determines how many attributes of a composite object are described.                                                                                                                                                                                                                                                                                                                                                                    |                 |
| Package                  | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                 |                 |
| Initial Value            | 20                                                                                                                                                                                                                                                                                                                                                                                                                                     |                 |
| Description              | <p>The variable <code>*describe-length*</code> controls how many attributes of a composite object the function <code>describe</code> describes.</p> <p>This means the number of elements of a sequence, entries in a hash table, slots of a structure instance, and so on.</p> <p>If <code>*describe-length*</code> is <code>nil</code> then <code>describe</code> describes all of the attributes. Use this value only with care.</p> |                 |
| Notes                    | The <code>describe</code> functionality is load-on-demand in the Lisp-Works image as shipped. Therefore if you have not done                                                                                                                                                                                                                                                                                                           |                 |

(require "describe") or called `describe`, \*`describe-length`\* may be unbound.

**See also** [describe](#)

\*describe-level\*

## **Variable**

**Summary** Controls the depth to which `describe` describes arrays, structures and conses.

## Package **lispworks**

### Initial Value

Description The variable **\*describe-level\*** controls the depth to which the function **describe** describes arrays, structures and conses.

Notes The `describe` functionality is load-on-demand in the Lisp-Works image as shipped. Therefore if you have not done `(require "describe")` or called `describe`, `*describe-level*` may be unbound.

**Example**

```

CL-USER 23 > (describe 1)
[... load output not shown ...]

1 is a BIT
DECIMAL 1
HEX 1
OCTAL 1
BINARY 1

CL-USER 24 > *describe-level*
1

CL-USER 25 > (defstruct foo a s d)
FOO

CL-USER 26 > (defmethod describe-object ((f foo) (s
stream))
 (format s "FOO ~S~%" f)
 (describe (foo-a f) s))
#<STANDARD-METHOD DESCRIBE-OBJECT NIL (FOO STREAM)
2068295C>

CL-USER 27 > (describe (make-foo :a (vector 1 2 3) :s
42))

FOO #S(FOO A #(1 2 3) S 42 D NIL)
#(1 2 3)

```

To make **describe** operate on objects inside the structure instance, increase the value of **\*describe-level\***:

```

CL-USER 28 > (setf *describe-level* 2)
2

CL-USER 29 > (describe (make-foo :a (vector 1 2 3) :s
42))

FOO #S(FOO A #(1 2 3) S 42 D NIL)
#(1 2 3) is a SIMPLE-VECTOR
 0 1
 1 2
 2 3

```

**describe**

## **\*describe-print-length\*** *Variable*

Summary      Specifies a print length for `describe` and `apropos`.

Package      `lispworks`

Initial Value      10

Description      If `*print-length*` is nil, `describe` and `apropos` bind `*print-length*` to the value of `*describe-print-length*`.

See also      `describe`

## **\*describe-print-level\*** *Variable*

Summary      Specifies a print level for `describe` and `apropos`.

Package      `lispworks`

Initial Value      10

Description      If `*print-level*` is nil, `describe` and `apropos` bind `*print-level*` to the value of `*describe-print-level*`.

See also      `describe`

## **dll-quit** *Function*

Summary      Makes a LispWorks dynamic library quit.

Package      `lispworks`

Signature      `dll-quit &key kill-all-processes timeout output force => result, quit-output`

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Arguments   | <i>kill-all-processes</i> A generalized boolean.<br><i>timeout</i> A positive integer or <code>nil</code> .<br><i>output</i> An output stream designator.<br><i>force</i> A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Values      | <i>result</i> <code>t</code> or <code>nil</code> .<br><i>quit-output</i> A string or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description | <p>The function <code>dll-quit</code> makes a LispWorks dynamic library (or DLL) quit on returning from the callback in which it was called. It must be called only:</p> <ul style="list-style-type: none"> <li>• In an image running as a dynamic library, meaning an image created by <code>save-image</code> with <code>:dll-exports</code> or by <code>deliver</code> with <code>:dll-exports</code>, and</li> <li>• Inside the dynamic scope of a callback into the dynamic library. That is, not in a process that was started by <code>process-run-function</code>.</li> </ul> <p><code>dll-quit</code> sets up the internal state such that just before returning into its caller in the LispWorks dynamic library it causes LispWorks to quit. After quitting the callback returns as normal. The library can be unloaded using <code>FreeLibrary</code>, or you can re-use it (without re-loading).</p> <p>By default <code>kill-all-processes</code> is <code>nil</code> which means that, if there are other running processes, <code>dll-quit</code> just returns <code>nil</code>. If <code>kill-all-processes</code> is non-<code>nil</code>, <code>dll-quit</code> tries to kill all the other processes, and if it succeeds, it quits.</p> <p>If <code>kill-all-processes</code> is true, <code>timeout</code> is a maximum time to wait after killing the other processes. It allows <code>timeout</code> seconds for all processes to die.</p> <p><code>dll-quit</code> should be called when no other processes are running, whether they were created by a callback or by <code>process-run-function</code>. If such processes exist, by default <code>dll-quit</code> does nothing and returns <code>nil</code>. If <code>force</code> is non-<code>nil</code>, <code>dll-</code></p> |

`quit` always tries to set LispWorks up for quitting. LispWorks will quit even after a failure to kill all other processes and complete any required shut down operations. A true value of `force` automatically implies `kill-all-processes` true. However, if any of the other processes is stuck in a foreign call, the quitting may fail to finish properly. The default value of `force` is `nil`.

If `output` is supplied, `dll-quit` generates output if it is called when other processes are still running, or a required shut down operation was not completed. `output` can be an output stream, `t` (interpreted as `*standard-output*`) or `nil`. If `output` is `nil`, `dll-quit` collects the output and returns it as second argument `quit-output`. Otherwise it writes the output to the stream and `quit-output` is `nil`.

The output contains a list of the other processes that are still running. If `kill-all-processes` or `force` was supplied, and killing the other processes failed, the output also contains backtraces of the other processes, and possibly other debugging information.

`result` is `t` on success: the LispWorks dynamic library is set to quit on returning from the callback. `result` is `nil` when other processes are running: the image is not set to quit.

`quit-output` contains the output which was generated when `output nil` was passed. Otherwise `quit-output` is `nil`.

If `dll-quit` is called inside a recursive foreign callback, the LispWorks dynamic library quits only when the outermost callback returns.

## Notes

1. `dll-quit` is intended for use when a LispWorks dynamic library is loaded by a main process which you (the LispWorks programmer) do not control. If you control the main process, then use `QuitLispWorks` instead.

It is expected that the main process will call into the dynamic library with some "shutdown" call, and then calls `FreeLibrary` to free the library. The shutdown call should close and free everything that needs to be closed or freed, call `dll-quit`, and return.

2. `dll-quit` is supported only where LispWorks can be a dynamic library. Currently this is in 32-bit LispWorks on Microsoft Windows, Intel Macintosh, Linux, x86/x64 Solaris and FreeBSD, and in 64-bit LispWorks on Windows, Intel Macintosh, Linux and x86/x64 Solaris.

## dotted-list-p

*Function*

Summary      Tests whether a `cons` is a list ending in a non-nil `cdr`.

Package      `lispworks`

Signature      `dotted-list-p list => bool`

Arguments      `list`      A list, which must be a `cons`.

Values      `bool`      A generalized boolean.

Description      The function `dotted-list-p` is a predicate which tests whether `list` (which must be a `cons`) is a list ending in a non-nil `cdr`. It returns a true value if this is the case, otherwise it returns `nil`.

## do-nothing

*Function*

Summary      Ignores its arguments and returns an unspecified value.

Package      `lispworks`

Signature      `do-nothing &rest ignore => unspecified`

Arguments      `ignore`      All arguments are ignored.

Values      `unspecified`      An unspecified value.

Description      The function `do-nothing` ignores its arguments and returns an unspecified value. It is useful as a function argument.

| <b>*enter-debugger-directly*</b> | <i>Variable</i>                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Summary                          | Controls direct entry into the Debugger tool.                                                                                                                                                                                                                                                                                                                                                                                                           |
| Package                          | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Initial value                    | <code>nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description                      | <p>The variable <code>*enter-debugger-directly*</code> is a generalized boolean which affects the behavior of the LispWorks IDE when an error is signalled outside of the Listener REPL.</p> <p>Value <code>nil</code> causes an error notifier window to be displayed (from which you can abort, report a bug, or raise a Debugger tool).</p> <p>A true value causes the Debugger tool to be displayed immediately, and no error notifier appears.</p> |
| Notes                            | Errors signalled in a Listener Read-Eval-Print loop are handled in the REPL and therefore <code>*enter-debugger-directly*</code> has no effect on the behavior in this case.                                                                                                                                                                                                                                                                            |

|                             |                                                                                               |
|-----------------------------|-----------------------------------------------------------------------------------------------|
| <b>environment-variable</b> | <i>Function</i>                                                                               |
| Summary                     | Reads the value of an environment variable from the environment table of the calling process. |
| Package                     | <code>lispworks</code>                                                                        |
| Signature                   | <code>environment-variable name =&gt; result</code>                                           |
| Arguments                   | <code>name</code> A string.                                                                   |
| Values                      | <code>result</code> A string or <code>nil</code> .                                            |

Description      The function `environment-variable` reads the environment variable specified by *name* and returns its value, or `nil` if the variable could not be found.

A `setf` method is also defined, allowing you to set the value of an environment variable:

```
(setf (environment-variable name) value)
```

If *value* is a string, then *name* is set to be *value*. If *value* is `nil` then *name* is removed from the environment table.

Example      In this first example the value of the environment variable `PATH` is returned:

```
(environment-variable "PATH")
```

The result is a string of all the defined paths:

```
"c:\\hqbin\\nt\\x86;c:\\hqbin\\nt\\x86\\perl;c:\\hqbin\\\nwin32;c:\\usr\\local\\bin;C:\\WINNT35\\system32;C:\\WI\nNT35;;C:\\MSTOOLS\\bin;C:\\TGS3D\\PROGRAM;c:\\program\nfiles\\devstudio\\sharedide\\bin\\ide;c:\\program\nfiles\\devstudio\\sharedide\\bin;c:\\program\nfiles\\devstudio\\vc\\bin;c:\\msdev\\bin;C:\\WINDOWS;C:\n\\WINDOWS\\COMMAND;C:\\WIN95\\COMMAND;C:\\MSINPUT\\MOUS\nE"
```

In the second example, the variable `MYTZONE` is found not to be in the environment table:

```
(environment-variable "MYTZONE")
```

```
NIL
```

It is set to be `GMT` using the `setf` method:

```
(setf (environment-variable "MYTZONE") "GMT")
```

## errno-value

## Function

Summary      Returns the current value of the UNIX variable `errno`.

|             |                                                                                                      |                                     |
|-------------|------------------------------------------------------------------------------------------------------|-------------------------------------|
| Package     | <b>lispworks</b>                                                                                     |                                     |
| Signature   | <b>errno-value =&gt; value</b>                                                                       |                                     |
| Arguments   | None.                                                                                                |                                     |
| Values      | <i>value</i>                                                                                         | The current value of <b>errno</b> . |
| Description | The function <b>errno-value</b> returns the current value of the UNIX variable <b>errno</b> .        |                                     |
| Notes       | <b>errno-value</b> is implemented only on UNIX/Linux/Mac OS X.                                       |                                     |
| Example     | <pre>USER 10 &gt; (errno-value) 2  USER 11 &gt; (get-unix-error 2) "no such file or directory"</pre> |                                     |

## example-compile-file

*Function*

Summary     Compiles a file in the `examples` folder to a temporary output file.

Package     `lispworks`

Signature    `example-compile-file file &rest args => output-truename,  
warnings-p, failure-p`

Arguments    `file`       A pathname designator.

`args`       Arguments passed to `compile-file`.

Values       `output-truename` A pathname or `nil`.

`warnings-p`    A generalized boolean.

`failure-p`    A generalized boolean.

Description    The function `example-compile-file` constructs the path to `file` in the `examples` folder of the LispWorks library, and a path to an output file in a temporary location which is likely to be writable.

It then calls `compile-file` with these paths as the `input-file` and `output-file`, also passing the other `args`, and returns the values returned by `compile-file`.

| Signature              | <code>execute-actions name-or-list &amp;rest keyword-value-pairs &amp;rest other-args =&gt;</code> |                  |
| Arguments              | <code>name-or-list</code>                                                                          | An action list   |
|                        | <code>keyword-value-pairs</code>                                                                   | See description. |
|                        | <code>other-args</code>                                                                            | A list.          |

Description      The `execute-actions` macro executes, in sequence, the actions on the specified list. If the action-list specified by *name-or-list* does not exist, then this is handled according to the value of `*handle-missing-action-list*`. Note that *name-or-list* is evaluated.

If a user-defined execution function was specified when the action list was defined, then it should accept the following arguments:

`(action-list other-args &rest keyword-value-pairs)`

Note that *other-args* is passed as a single list.

If a user-defined execution function was not specified when the action list was defined, then the following default mapping occurs. Each action's data is invoked via apply on *other-args*:

`(apply data other-args)`

This behavior is modified by the keyword-value-pairs, thus:

- If the keyword parameter `:ignore-errors-p` is non-nil, any otherwise-unhandled errors signalled inside the execution of that function will be trapped, and a warning issued. Execution continues with the next action-item. If `:ignore-errors-p` is `nil` (or not specified), then the error is not trapped.
- If the keyword parameter `:post-process` is non-nil, the first value returned by each action is handled, according to `:post-process`, thus:

|                       |                                                                                                                                    |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>:collect</code> | collect values into list                                                                                                           |
| <code>:and</code>     | return <code>t</code> only if all values are <code>t</code> . Return <code>nil</code> immediately if any value is <code>nil</code> |
| <code>:or</code>      | return first non-nil value                                                                                                         |

| Values                      | <code>bool</code>                                                                                            | <code>t</code> if <i>object</i> is an extended character; <code>nil</code> otherwise. |
| Description                 | This is the predicate for extended characters.                                                               |                                                                                       |

See also **`extended-character`**

## **extended-char-p** *Function*

Summary Tests if an object is an extended character.

Package **`lispworks`**

Signature **`extended-char-p object => bool`**

Arguments ***object*** The object to be tested.

Values ***bool*** **`t`** if *object* is an extended character; **`nil`** otherwise.

Description This is also the predicate for extended characters, only with standard spelling.

See also **`extended-char`**  
**`extended-character-p`**

## **\*external-formats\*** *Variable*

Summary A list of the names of the defined external formats.

Package **`lispworks`**

Initial value Microsoft Windows platforms:

```
(WIN32:CODE-PAGE FLI::LATIN-1-WCHAR FLI:ASCII-WCHAR
:MACOS-ROMAN :UTF-8 :GBK :WINDOWS-CP936 EXTERNAL-
FORMAT:DOUBLE-BYTE-TABLE-LOOKUP :JIS :EUC-JP :SJIS
:LATIN-1-TERMINAL :UNICODE :LATIN-1-SAFE :LATIN-1-
CHECKED :EUC :SHIFT-JIS :NIHONGO-MS :NIHONGO-EUC
:NIHONGO-JIS CHARACTER EXTERNAL-FORMAT::BYTE-SWAPPED-
SIMPLE-CHARACTER EXTERNAL-FORMAT::RAW-SIMPLE-CHARACTER
EXTERNAL-FORMAT::RAW-BASE-CHARACTER :ASCII-TERMINAL
:ASCII :LATIN-1)
```

On all other platforms:

```
(FLI::LATIN-1-WCHAR FLI:ASCII-WCHAR :MACOS-ROMAN :UTF-8
:GBK :WINDOWS-CP936 EXTERNAL-FORMAT:DOUBLE-BYTE-TABLE-
LOOKUP :JIS :EUC-JP :SJIS :LATIN-1-TERMINAL :UNICODE
:LATIN-1-SAFE :LATIN-1-CHECKED :EUC :SHIFT-JIS
:NIHONGO-MS :NIHONGO-EUC :NIHONGO-JIS EXTERNAL-
FORMAT::HOST-PORTABLE EXTERNAL-FORMAT::LATIN-PORTABLE
CHARACTER EXTERNAL-FORMAT::BYTE-SWAPPED-SIMPLE-
CHARACTER EXTERNAL-FORMAT::RAW-SIMPLE-CHARACTER
EXTERNAL-FORMAT::RAW-BASE-CHARACTER :ASCII-TERMINAL
:ASCII :LATIN-1)
```

**Description**      The variable **\*external-formats\*** contains a list of the names of the defined external formats.

The platform-specific external format names are:

**code-page**

Uses the encoding in the Microsoft Windows code page specified by the **:id** parameter.

**latin-portable**

Intended for use when communicating with X servers, for example when passing XLFD names. Uses the X Portable Character Set.

**host-portable**

A synonym for **latin-portable**.

## **file-directory-p** *Function*

|             |                                                                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Tests for the presence of a directory.                                                                                                                                          |
| Package     | <code>lispworks</code>                                                                                                                                                          |
| Signature   | <code>file-directory-p pathname =&gt; bool</code>                                                                                                                               |
| Arguments   | <code>pathname</code> A pathname, string, or file-stream.                                                                                                                       |
| Values      | <code>bool</code> If <code>t</code> , the pathname represented by pathname exists and is a directory. If <code>nil</code> , it either does not exist, or it is not a directory. |
| Description | <code>file-directory-p</code> tests whether the pathname represents a directory.                                                                                                |
| Example     | <pre>CL-USER 70 &gt; (file-directory-p "~") T  CL-USER 71 &gt; (file-directory-p ".login") NIL</pre>                                                                            |

| <b>find-regexp-in-string</b> | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary                      | Matches a regular expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Package                      | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Signature                    | <code>find-regexp-in-string pattern <i>string</i> &amp;key <i>start end from-end case-sensitive</i> =&gt; <i>pos, len</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Description                  | <p>The function <code>find-regexp-in-string</code> searches the string <code>string</code> for a match for the regular expression <code>pattern</code>. The index in <code>string</code> of the start of the first match is returned in <code>pos</code>, and the length of the match is <code>len</code>.</p> <p>If <code>from-end</code> is <code>nil</code> (the default value) then the search starts at index <code>start</code> and ends at index <code>end</code>. <code>start</code> defaults to 0 and <code>end</code> defaults to <code>nil</code>. If <code>from-end</code> is true, then the search direction is reversed.</p> <p><code>pattern</code> should be a precompiled regular expression object or a string. If <code>pattern</code> is a string then <code>find-regexp-in-string</code> first makes a precompiled regular expression object. This operation allocates, therefore if you need to repeatedly call <code>find-regexp-in-string</code> with the same pattern, it is better to call <code>precompile-regexp</code> once and pass its result, a pre-compiled regular expression object, as <code>pattern</code>.</p> |

`case-sensitive` controls whether a string *pattern* is precompiled as a case sensitive or case insensitive search. A true value other than `:default` means a case sensitive search. The value `nil` means a case insensitive search. The default value of `case-sensitive` is `:default` which means that a string *pattern* is compiled with case sensitivity according to the value of the Editor variable `DEFAULT-SEARCH-KIND`.

The regular expression syntax used by `find-regexp-in-string` is similar to that used by Emacs, as described in the "Regular expression syntax" section of the *LispWorks Editor User Guide*.

#### Example

This form allocates several regular expression objects:

```
(loop with pos = 0
 with len = 0
 while pos
 do (multiple-value-setq (pos len)
 (find-regexp-in-string "[0,2,4,6,8]"
 "0123456789"
 :start (+ pos len)))
 when pos
 do (format t "~&Match at pos ~D len ~D~%"
 pos len))
```

This form does the same matching but allocates just one pre-compiled regular expression object:

```
(loop with pattern = (precompile-regexp "[0,2,4,6,8]")
 with pos = 0
 with len = 0
 while pos
 do (multiple-value-setq (pos len)
 (find-regexp-in-string pattern "0123456789"
 :start (+ pos len)))
 when pos do (format t "~&Match at pos ~D len ~D~%"
 pos len))
```

| Arguments                   | <i>object</i>                                                             | The object to be inspected.                                                           |
|                             | <i>mode</i>                                                               | Name of a mode, or nil. nil defines the default inspection format for <i>object</i> . |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | Returns five values: <i>names</i> , <i>values</i> , <i>getter</i> , <i>setter</i> and <i>type</i> . <i>names</i> and <i>values</i> are the two lists displayed in columns in the inspector window. <i>getter</i> is ignored. <i>setter</i> is a function used to update slot values. <i>type</i> is displayed at the foot of the inspector window.                                                                                                                                                                                                                                                     |
| Description | This generic function allows you to customize the LispWorks IDE Inspector by adding new formats (corresponding to different values of mode) in which instances of a particular class can be inspected. Mode <code>nil</code> is the default mode, which is always present (it can be overwritten).<br><br>LispWorks includes methods for:<br><br><code>(get-inspector-values (object nil))<br/>(get-inspector-values (standard-object nil))<br/>(get-inspector-values (structured-object nil))<br/>(get-inspector-values (sequence nil))<br/>(get-inspector-values cons nil))</code><br><br>and so on. |
| Example     | This example allows inspection of a CLOS object, displaying only direct slots from a chosen class in its class precedence list. This can be useful when an object inherits many slots from superclasses, and the inherited slots are of no interest.                                                                                                                                                                                                                                                                                                                                                   |

```
(defmethod lispworks:get-inspector-values

 new-value))
 (format nil "~a - direct slots as ~a"
 (class-name object-class)
 (class-name class))))))
```

|             | <i>Function</i>                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns the text associated with a given error.                                                                             |
| Package     | <b>lispworks</b>                                                                                                            |
| Signature   | <b>get-unix-error number =&gt; error</b>                                                                                    |
| Arguments   | <b>number</b> The <b>errno</b> value whose text is required.                                                                |
| Values      | <b>error</b> The text associated with the error.                                                                            |
| Description | The function <b>get-unix-error</b> returns the text associated with the specified value of the UNIX variable <b>errno</b> . |
| Notes       | <b>get-unix-error</b> is implemented only on UNIX/Linux/Mac OS X/FreeBSD.                                                   |
| See also    | <b>errno-value</b>                                                                                                          |

|               | <i>Variable</i>                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package       | <b>lispworks</b>                                                                                                                                                                        |
| Summary       | Determines the search utility used by <b>Grep</b> searches in the Search Files tool in the LispWorks IDE.                                                                               |
| Initial Value | <b>"grep"</b> on Unix/Linux/Mac OS X/FreeBSD platforms.<br><b>nil</b> on Windows.                                                                                                       |
| Description   | If the value is a string, it is the search utility to run in the Search Files tool.<br><br>If the value is <b>nil</b> , then the value of<br><br><b>(sys:lispworks-file "etc/grep")</b> |

is expected to be an executable, which is run. On Windows a suitable `grep.exe` is included with LispWorks in this location.

The search utility is passed arguments constructed using `*grep-command-format*` and `*grep-fixed-args*`.

See the *LispWorks IDE User Guide* for more information about the Search Files tool.

See also      `*grep-command-format*`  
`*grep-fixed-args*`

### **`*grep-command-format*`** *Variable*

Package      `lispworks`

Summary      The format string used to construct the arguments passed to the Search Files tool to perform a **Grep** search.

Initial Value      `"cd '~a'; ~a ~a ~a /dev/null"` on Unix/Linux/Mac OS X.

`"~a ~a ~a NUL"` on Windows.

Description      On Unix/Linux/Mac OS X the first format argument is the current directory.

The remainder of the format arguments are:

- the value of `*grep-command*` or, if this is `nil`, the value of `(sys:lispworks-file "etc/grep")`.
- the value of `*grep-fixed-args*`.
- the arguments you specify.

See the *LispWorks IDE User Guide* for more information about the Search Files tool.

\*grep-fixed-args\*

**\*grep-fixed-args\*** *Variable*

## Package **lispworks**

**Summary** Arguments added to the command string of a **Grep** search in the Search Files tool.

Initial Value      " -n "

|             |                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The variable <b>*grep-fixed-args*</b> provides arguments added to a <b>Grep</b> command string in the Search Files tool. The value should ensure that the line number is output at the start of each match. |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

See the *LispWorks IDE User Guide* for more information about the Search Files tool.

\*handle-existing-action-in-action-list\* *Variable*

**Summary** Contains keywords determining behavior on exceptions raised when an action definition already exists in a given action list.

## Package lispworks

Initial value (:warn :redefine)

Description The variable `*handle-existing-action-in-action-list*` is a list containing one of `:warn`, or `:silent`, determining whether to notify the user, and one of `:skip`, or `:redefine`.

to determine what to do about an action definition when the action already exists in the given action list.

It is used by `define-action`.

See also [define-action](#)

### \*handle-existing-action-list\*

## *Variable*

**Summary** Contains keywords determining what to do about a given action list operation when the action list already exists.

## Package lispworks

Initial value ( :warn :skip )

Description A list containing either `:warn` or `:silent`, determining whether to notify the user, and either `:skip` or `:redefine` to determine what to do about an action list operation when the action list already exists. The initial value is `(:warn :skip)`.

It is used by the macro `define-action-list`.

See also [define-action-list](#)

**\*handle-missing-action-list\***

## Variable

**Summary** Defines how to handle an operation on a missing action list.

## Package lispworks

Signature \*handle-missing-action-list\*

Initial value : error

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Description   | <p>The variable <code>*handle-warn-on-redefinition*</code> specifies what action should be taken on defining external symbols in certain packages. It is designed to protect against (re)definition of symbols in implementation packages.</p> <p>The protected packages are those specified in the variable <code>*packages-for-warn-on-redefinition*</code>.</p> <p>If <code>*handle-warn-on-redefinition*</code> is set to <code>:warn</code> then you are warned. If it is set to <code>:quiet</code> or <code>nil</code>, the definition is done quietly. If, however, it is set to <code>:error</code>, then LispWorks signals an error.</p> |

| Summary                | Print each file of a system to a printer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Package                | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Signature              | <code>hardcopy-system system-name &amp;key command simulate =&gt; nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Arguments              | <p><code>system-name</code> A symbol representing the name of the system. The system must have been defined using the <code>defsystem</code> macro.</p> <p><code>simulate</code> If <code>nil</code> or not present then <code>hardcopy-system</code> works silently. Otherwise a plan of the actions which <code>hardcopy-system</code> intends to carry out is printed. What happens next depends on the value of <code>simulate</code>:</p> <ul style="list-style-type: none"> <li><code>t</code> — do nothing.</li> </ul> |

**:ask** — you are asked, using **y-or-n-p**, if you want the plan to be carried out.

**:each** — **hardcopy-system** displays each action in the plan one at a time, and asks you if you want to carry out this particular action. The answer executes the rest of the plan without further prompting, **e** returns from **hardcopy-system** without further processing, and **y** and **n** work as expected.

Values      **hardcopy-system** returns **nil**.

Examples     

```
(hardcopy-system 'blackboard)
(hardcopy-system 'tms :simulate :ask :command "lpr")
```

Notes        By default, **hardcopy-system** uses **\*print-command\*** as the command sent to the shell.

## **\*init-file-name\*** *Variable*

Summary      The default user initialization file.

Package      **lispworks**

Initial value    **"~/.lispworks"**

Description     The variable **\*init-file-name\*** is the name of the default user initialization file.

However, if the user initialization file is specified by either:

- the command line argument **-init**, or

- user preferences (as set via the Preferences dialog in the LispWorks IDE)

then the value of `*init-file-name*` is not used.

### **\*inspect-through-gui\*** *Variable*

|               |                                                                                                                                                                                                                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | Controls what <code>inspect</code> does in the development environment.                                                                                                                                                                                                                                                                       |
| Package       | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                        |
| Initial Value | <code>nil</code>                                                                                                                                                                                                                                                                                                                              |
| Description   | <p>The variable <code>*inspect-through-gui*</code> controls what <code>inspect</code> does in the development environment.</p> <p>When the value is <code>nil</code>, <code>inspect</code> uses a command line interface in the REPL.</p> <p>When the value is true, <code>inspect</code> invokes an Inspector tool in the LispWorks IDE.</p> |

### **lisp-image-name** *Function*

|                   |                                                                                                                                               |                   |           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-------------------|-----------|
| Summary           | Returns the name of the running image.                                                                                                        |                   |           |
| Package           | <code>lispworks</code>                                                                                                                        |                   |           |
| Signature         | <code>lisp-image-name =&gt; name</code>                                                                                                       |                   |           |
| Arguments         | None.                                                                                                                                         |                   |           |
| Values            | <table style="width: 100%; border-collapse: collapse;"> <tr> <td style="width: 30%;"><code>name</code></td> <td>A string.</td> </tr> </table> | <code>name</code> | A string. |
| <code>name</code> | A string.                                                                                                                                     |                   |           |
| Description       | The function <code>lisp-image-name</code> returns a string representing the full path to the running LispWorks image. The example             |                   |           |

below is in typical LispWorks for Windows and LispWorks for Linux installations. In resaved and delivered images (including dynamic libraries such as Windows DLLs), the appropriate path is returned.

Example

On Windows:

```
CL-USER 1 > (lisp-image-name)
"C:\\Program Files\\LispWorks\\lispworks-6-1-0-x86-
win32.exe"
```

On Linux:

```
CL-USER 1 > (lisp-image-name)
"/usr/bin/lispworks-6-1-0-x86-linux"
```

See also

**\*line-arguments-list\***

**\*lispworks-directory\***

*Variable*

Summary

The main LispWorks installation directory.

Package

**lispworks**

Initial value

The initial value is

`#P"/usr/lib/lispworks/"` on Unix.

`#P"/usr/local/lib/LispWorks/"` on Linux (for an installation from the tar archive) x86/x64 Solaris or FreeBSD.

`#P"C:\Program Files\LispWorks\"` on Microsoft Windows.

`#P"/Applications/LispWorks 6.1/Library/"` on Mac OS X.

Note however that the value can be set when configuring an image or on startup.

|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The variable <code>*lispworks-directory*</code> holds the name of the directory where various files important for the running of LispWorks are located.</p> <p>When LispWorks starts in a directory which contains an appropriate numbered subdirectory such as <code>lib/6-1-0-0/</code>, then it assumes this is the LispWorks installation directory and sets <code>*lispworks-directory*</code> accordingly. Additionally, LispWorks for Macintosh running on Cocoa looks for such a subdirectory in the <code>Library</code> folder alongside its application bundle, and if found it sets <code>*lispworks-directory*</code> accordingly.</p> <p>On non-Windows platforms, LispWorks then consults the Unix environment variable <code>LISPWORKS_DIRECTORY</code>. If this is set, then <code>*lispworks-directory*</code> is set accordingly.</p> <p>The <code>lib/6-1-0-0/</code> subdirectory of <code>*lispworks-directory*</code> should include these subdirectories:</p> <ul style="list-style-type: none"><li><code>config</code>, which contains the configuration files.</li><li><code>patches</code>, which contains any public (numbered) patches that are distributed by LispWorks Ltd.</li><li><code>private-patches</code>, which is the place to put private (named) patches that are sent to you by Lisp Support.</li><li><code>postscript</code>, which contains configuration files for printing using the CAPI printing library. See “Configuring the printer” on page 144 for more information on printer configuration.</li><li><code>examples</code>, which contains various files of example code.</li></ul> <p>Other directories are <code>etc</code>, <code>load-on-demand</code> and <code>manual</code>. There is also <code>app-defaults</code> for platforms where Motif is supported.</p> |

| Arguments   | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Values      | Returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description | <p>Loads into the image all appropriate files from the directory <code>patches</code> in the directory determined by <code>*lispworks-directory*</code>, and then loads the file <code>private-patches/load.lisp</code> where load forms for any private patches may be placed. When the appropriate patches have successfully been loaded, the updated version of the image can be saved using <code>save-image</code>.</p> <p>You should call <code>load-all-patches</code> before starting the Lisp-Works IDE. Thus, you normally place the call to this function in your <code>.lispworks</code> file.</p> <p>The system expects all patches to be loaded sequentially. If a patch is missing, there is a warning message. In this situation, it is advisable to contact Lisp Support to obtain a copy of the missing patch.</p> |

|         | <i>Function</i>                                                                                                                               |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Summary | Load each file of a system into the Lisp image if either the file has not been loaded, or the file has been written since it was last loaded. |
| Package | <code>lispworks</code>                                                                                                                        |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Signature | <code>load-system system-name &amp;key force simulate source-only target-directory =&gt; nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Arguments | <p><i>system-name</i> A symbol representing the name of the system. The system must have been defined using the <code>defsystem</code> macro.</p> <p><i>force</i> If <code>t</code> then all the files in the system are loaded regardless. (This argument was formerly called <code>force-p</code>. The old name is currently still accepted for compatibility.)</p> <p><i>simulate</i> If <code>nil</code> or not present then <code>load-system</code> works silently. Otherwise a plan of the actions which <code>load-system</code> intends to carry out is printed. What happens next depends on the value of <i>simulate</i>:</p> <ul style="list-style-type: none"> <li><code>t</code> — do nothing.</li> <li><code>:ask</code> — you are asked, using <code>y-or-n-p</code>, if you want to carry out the plan.</li> <li><code>:each</code> — <code>load-system</code> displays each action in the plan one at a time, and asks you if you want to carry out this particular action. The answer executes the rest of the plan without further prompting, <code>e</code> returns from <code>load-system</code> without further processing, and <code>y</code> and <code>n</code> work as expected.</li> </ul> <p><i>source-only</i> If <code>t</code> the source files of the system are loaded. This only applies to file types where it makes sense to load a source file.</p> <p><i>target-directory</i> This is the directory to search for the object files. If the object file cannot be found here then the source file from the system's default directory are loaded.</p> |
| Examples  | <code>(load-system 'blackboard)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <p>For Lisp files <code>load-system</code> loads the object file (if it exists) into the image, unless over-ridden by the <code>:source-only</code> keyword argument. This behavior can be changed so that the newest file (whether source or object) is loaded by setting the variable <code>*load-source-if-newer*</code> to <code>t</code>.</p> <p>C source files, for example <code>foo.c</code>, can be included in a system (see the use of <code>:default-type</code> and <code>:type</code> in <code>defsystem</code>). The corresponding object file name is <code>foo.so</code> on Linux, and on Unix it is <code>foon.o</code> where <code>n</code> is a platform-specific integer. On Windows the object file name is <code>foo.dll</code>.</p> |

## **make-unregistered-action-list** *Function*

|           |                                                                                                                                                                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | Makes an unregistered action list.                                                                                                                                                                                                             |
| Package   | <code>lispworks</code>                                                                                                                                                                                                                         |
| Signature | <code>make-unregistered-action-list &amp;key documentation sort-time dummy-actions default-order execution-function =&gt;</code>                                                                                                               |
| Arguments | <p><i>documentation</i> A string.</p> <p><i>sort-time</i> One of <code>:execute</code> or <code>:define-action</code>.</p> <p><i>dummy-actions</i> A list.</p> <p><i>default-order</i> A list.</p> <p><i>execution-function</i>A function.</p> |

Description      Return an action-list not registered in the global registry of lists. The keyword arguments are as for `define-action-list`.

The *documentation* string allows you to provide documentation for the action list.

*sort-time* is a keyword specifying when added actions are sorted for the given list — either `:execute` or `:define-action` (see `*default-action-list-sort-time*`).

*dummy-actions* is a list of action-names that specify placeholder actions; they cannot be executed and are constrained to the order specified in this list, for example

```
'(:beginning :middle :end)
```

*default-order* specifies default ordering constraints for subsequently defined action-items where no explicit ordering constraints are specified. An example is

```
'(:after :beginning :before :end)
```

*execution-function* specifies a user-defined function accepting arguments of the form:

*(the-action-list other-args-list &rest keyword-value-pairs)*

where the two required arguments are the action-list and a list of additional arguments passed to `execute-actions`, respectively. The remaining arguments are any number of keyword-value pairs that may be specified in the call to `execute-actions`. If no execution function is specified, then the default execution function will be used to execute the action-list.

## pathname-location

*Function*

Summary      Returns the location of a file.

Signature      **pathname-location pathname => location**

Arguments      **pathname**      A pathname designator.

Values      **location**      A pathname.

Description      The function **pathname-location** returns a pathname *location* that represents the directory where the file *pathname* resides. Each of the name, type and version components of *location* are **nil**.

Example      Due to the ANSI Common Lisp definition of the **directory** function and the fact that LispWorks returns fully specified truenames, the form

```
(directory (truename "/tmp/"))
```

will always signal an error or return the list (#P"/tmp/"). To obtain the contents of the /tmp directory, use the form

```
(directory (pathname-location (truename "/tmp/")))
```

**directory**

## precompile-regexp

*Function*

Summary      Precompiles a regular expression object.

## **\*print-nickname\*** *Variable*

**Summary** Controls the package prefix used when a symbol is printed.

**Package** `lispworks`

**Initial Value** `nil`

**Description** The variable `*print-nickname*` controls which package prefix is used when a symbol is printed and the symbol's package needs to be output.

If `*print-nickname*` is true and the package has at least one nickname, then the first of the nicknames (that is, the first nickname in the list returned by `package-nicknames`) is output. Otherwise, the package name is output.

## **\*prompt\*** *Variable*

**Summary** Defines the LispWorks listener prompt.

**Package** `lispworks`

**Initial Value** `"~%~A ~D~ [~:;~:* : ~D~] > "`

**Description** The variable `*prompt*` defines the LispWorks listener prompt. Its value can be a:

Function designator

A function of zero arguments which should return the prompt as a string.

String A format string with processing three arguments: the current package name, the next history number, and the debug level.

| <code>confirm</code>         | A generalized boolean.                                                                                                                                                                                                                                                                                  |                     |             |                      |                        |                              |                        |                     |                        |
| <code>ignore-errors-p</code> | A generalized boolean.                                                                                                                                                                                                                                                                                  |                     |             |                      |                        |                              |                        |                     |                        |
| <code>return</code>          | A generalized boolean.                                                                                                                                                                                                                                                                                  |                     |             |                      |                        |                              |                        |                     |                        |
| Values                       | <code>quit</code> does not return, or returns <code>t</code> .                                                                                                                                                                                                                                          |                     |             |                      |                        |                              |                        |                     |                        |
| Description                  | <p>The function <code>quit</code> exits LispWorks unless the user cancels the operation.</p> <p>There are two stages which may allow the user the chance to cancel.</p>                                                                                                                                 |                     |             |                      |                        |                              |                        |                     |                        |

1. First the action items of the action list "`Confirm when quitting image`" are run. If any action item returns `nil`, then LispWorks does not exit.
2. Otherwise, if `confirm` is true (the default value is `nil`) then a question like  
`"Do you really want to exit LispWorks?"` is presented to the user. If the answer No is supplied, then LispWorks does not exit. Otherwise, the action items of the action list "`When quitting image`" are run, and then LispWorks exits, and the value `status` is returned to the Operating System as the exit value of the LispWorks process. The default value of `status` is 0.

If `ignore-errors-p` is true, then any error signalled during the running of the action list items or the confirm prompt is ignored and `quit` proceeds to exit the image. If `ignore-errors-p` is `nil` and an error is signalled during the running of the action list items, then a restart is available allowing the user to choose to continue to exit the image. The default values of `ignore-errors-p` is `nil`.

If `return` is true and LispWorks is going to exit, then `quit` returns `t`. This can be used if you want some other Lisp process to kill the current one later, rather than it self-destructing immediately. This can be useful to allow more precise control over process termination. If `return` is `nil` then `quit` does not return. The default value of `return` is `nil`.

|       |                                                                                                                                                                                                                                                                                                                                                                                                  |

| Notes | On Cocoa, when you define your own application menu (by passing <code>:application-menu</code> when making the application interface), the <code>Quit</code> menu item needs to call <code>capi:destroy</code> on the application interface, rather than <code>quit</code> . See <code>capi:cocoa-default-application-interface</code> in the <i>CAPI Reference Manual</i> for more information. |

| Arguments   | <table border="0"> <tr> <td>vars</td><td>The variables to be rebound.</td></tr> <tr> <td>body</td><td>A body of forms, the variables in which should be unique.</td></tr> </table>                                                                                                                   | vars | The variables to be rebound. | body | A body of forms, the variables in which should be unique. |
| vars        | The variables to be rebound.                                                                                                                                                                                                                                                                         |      |                              |      |                                                           |
| body        | A body of forms, the variables in which should be unique.                                                                                                                                                                                                                                            |      |                              |      |                                                           |
| Values      | Returns the body wrapped in a form that creates unique names for each variable.                                                                                                                                                                                                                      |      |                              |      |                                                           |
| Description | Returns the <i>body</i> wrapped in a form which creates a unique name for each of the variables (compare with <code>gensym</code> ) and binds these names to the values of the variables. This ensures that the body can refer to the variables without name clashes with other variables elsewhere. |      |                              |      |                                                           |
| Example     | <p>After defining</p> <pre>(defmacro lister (x y)   (rebinding (x y)     '(list ,x ,y)))</pre> <p>the form <code>(lister i j)</code> macroexpands to</p> <pre>(LET* ((#:X-77 I)        (#:Y-78 J))   (LIST #:X-77 #:Y-78))</pre>                                                                     |      |                              |      |                                                           |
| See also    | <code>with-unique-names</code>                                                                                                                                                                                                                                                                       |      |                              |      |                                                           |

|             | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns a list of symbols that match a supplied regular expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Package     | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Signature   | <code>regexp-find-symbols <i>regexp-string</i> &amp;key <i>case-sensitive</i> <i>packages</i><br/><i>test external-only</i> =&gt; <i>symbols</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Arguments   | <p><i>regexp-string</i> A string.</p> <p><i>case-sensitive</i> A boolean.</p> <p><i>packages</i> A list of package designators, a single package designator, or the keyword :<code>all</code>.</p> <p><i>test</i> A function of one argument returning a boolean result.</p> <p><i>external-only</i> A generalized boolean.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Values      | <i>symbols</i> A list of symbols.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description | <p>The function <code>regexp-find-symbols</code> returns a list of symbols that match the regular expression in <i>regexp-string</i>. <i>case-sensitive</i> determines whether the match is case sensitive. The default value of <i>case-sensitive</i> is <code>nil</code>.</p> <p><i>packages</i> specifies in which packages to search. The default value of <i>packages</i> is :<code>all</code>, meaning search in all packages.</p> <p><i>test</i>, if supplied, must be a function of one argument, which returns <code>t</code> if the argument should be returned, and <code>nil</code> otherwise. The function <i>test</i> is applied to each symbol that matches <i>regexp-string</i>, and if it returns <code>nil</code> the symbol is not included in the returned value <i>symbols</i>. If <i>test</i> is <code>nil</code> all matches are returned. The default value of <i>test</i> is <code>nil</code>.</p> |

*external-only*, if true, specifies that only external symbols should be checked, which makes the search much faster. The default value of *external-only* is `nil`.

The regular expression syntax used by `regexp-find-symbols` is similar to that used by Emacs, as described in the "Regular expression syntax" section of the *LispWorks Editor User Guide*.

Examples To find all exported symbols that start with DEF:

```
(lw:regexp-find-symbols "^def" :external-only t)
```

To find all symbols that contain lower case "slider":

```
(regexp-find-symbols "slider" :case-sensitive t)
```

`find-regexp-in-string`

## remove-advice *Function*

Summary Remove a piece of advice.

Package `lispworks`

Signature `remove-advice dspec name => nil`  
`dspec ::= fn-name |`  
`macro-name |`  
`(method generic-fn-name [(class*)])`

Arguments `dspec` Specifies the functional definition to which the piece of advice belongs. The specification contains the name of the associated function. In the case of a method the list of classes is used to identify from which particular method the advice should come. This list must correspond exactly with the classes

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | corresponding to the specialized parameters for some method belonging to the generic function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>name</i> | A symbol naming the piece of advice to be removed. Since several pieces of advice may be attached to a single functional definition, the name is necessary to indicate which one is to be removed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Values      | <code>remove-advice</code> returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description | <code>remove-advice</code> is the function used to remove a piece of advice. Advice is a way of altering the behavior of functions. Pieces of advice are associated with a function using <code>defadvice</code> . They define additional actions to be performed when the function is invoked, or alternative code to be performed instead of the function, which may or may not access the original definition. As well as being attached to ordinary functions, advice may be attached to methods and to macros (in this case it is in fact associated with the macro's expansion function).<br><br><code>hcl:delete-advice</code> is a macro, identical in effect to <code>remove-advice</code> , except that you do not need to quote the arguments. |
| Notes       | <code>remove-advice</code> is an extension to Common Lisp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Values             | <b>double-float</b> A <b>double-float</b> with <b>single-float</b> precision.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description        | <p>The argument is rounded to single-precision format (32 bits) and returned as a <b>double-float</b> (64 bits). This function allows you to model the rounding behavior of a machine or implementation that performs 32-bit floating point arithmetic.</p> <p>The default size on Windows and Linux is 64 bits as specified by the IEEE standard.</p> <p>LispWorks supports 3 floating point formats, <b>short-float</b>, <b>single-float</b> and <b>double-float</b>. If this function is called with a <b>single-float</b> or a <b>short-float</b>, it returns the equivalent <b>double-float</b>, that is, it is the same as doing</p> <pre>(coerce float 'double-float)</pre> |
| Compatibility note | LispWorks 4.4 and previous on Windows and Linux platforms supports just one floating point format. In LispWorks 5.0 and later, three floating point formats are supported on all platforms.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Signature                                 | <code>set-default-character-element-type type =&gt; type-defaults</code>                                                                                                                         |                   |                                                                                                                                   |
| Arguments                                 | <table> <tr> <td><code>type</code></td> <td>A character type. This can take any of the values <code>base-char</code>; <code>lw:simple-char</code> and <code>character</code></td> </tr> </table> | <code>type</code> | A character type. This can take any of the values <code>base-char</code> ; <code>lw:simple-char</code> and <code>character</code> |
| <code>type</code>                         | A character type. This can take any of the values <code>base-char</code> ; <code>lw:simple-char</code> and <code>character</code>                                                                |                   |                                                                                                                                   |
| Values                                    | <code>type-defaults</code> The new value of <code>lw:*default-character-element-type*</code> .                                                                                                   |                   |                                                                                                                                   |
| Description                               | The function <code>set-default-character-element-type</code> sets the value of <code>lw:*default-character-element-type*</code> ,                                                                |                   |                                                                                                                                   |

ensuring that the system's internal state is also updated accordingly.

If you are running an existing 8-bit application you will only need to have this in your site or user configuration file:

```
(lw:set-default-character-element-type 'base-char)
```

It would be a mistake to call this function in a loadable package and it is not intended to be called while running code. In particular, it is global, not thread-specific.

Hence we consider `lw:*default-character-element-type*` a parameter.

## **set-quit-when-no-windows**

## *Function*

Summary      Overrides the `:quit-when-no-windows` keyword argument to `deliver`.

Signature     `set-quit-when-no-windows on`

Arguments     `on`                 `nil`, `t` or the keyword `:check`

Description     The function `set-quit-when-no-windows` can be used at runtime in a delivered application to override the value of the `:quit-when-no-windows` keyword to `deliver`. This can be useful if the application runs in various modes, some with windows and some without. It has no effect in a non-delivered application.

If `on` is `nil`, then the application will not quit merely because there are no remaining open windows.

If *on* is `t`, then the application will quit when there are no remaining open windows after the application has opened at least one CAPI window.

If *on* is `:check`, then the application will quit immediately if there are no open windows at the current time. Unlike with `:quit-when-no-windows t`, this occurs even if the application has not opened any CAPI windows so far. If there are open windows currently, then it turns on quitting like when *on* is `t`.

See also      `:quit-when-no-windows` in the *LispWorks Delivery User Guide*

## **simple-base-string-p** *Function*

Summary      Tests if an object is a simple base string.

Package      `lispworks`

Signature      `simple-base-string-p object => bool`

Arguments      `object`      The object to be tested.

Values      `bool`      `t` if *object* is a simple base string; `nil` otherwise.

Description      This is the predicate for simple base strings.

See also      `simple-base-string`

## **simple-char** *Type*

Summary      The simple character type.

|             |                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>lispworks</code>                                                                                                 |
| Signature   | <code>simple-char</code>                                                                                               |
| Description | The type of simple characters (standard term for chars with null implementation-defined attributes, that is, no bits). |

| <b>simple-char-p</b> |                                                            | <i>Function</i>                                                                    |
|----------------------|------------------------------------------------------------|------------------------------------------------------------------------------------|
| Summary              |                                                            | Tests if an object is a simple character.                                          |

| Arguments            | <i>object</i>                                              | The object to be tested.                                                           |
| Values               | <i>bool</i>                                                | <code>t</code> if <i>object</i> is a simple character; <code>nil</code> otherwise. |
| Description          | The predicate for simple characters.                       |                                                                                    |
| See also             | <code>simple-char</code>                                   |                                                                                    |

| <b>simple-text-string</b> |                                               | <i>Type</i>                                                 |
|---------------------------|-----------------------------------------------|-------------------------------------------------------------|
| Summary                   |                                               | The simple text string type.                                |
| Package                   | <code>lispworks</code>                        |                                                             |
| Signature                 | <code>simple-text-string <i>length</i></code> |                                                             |
| Arguments                 | <i>length</i>                                 | The length of the string (or <code>*</code> , meaning any). |

Description This is the simple version of `text-string`, that is, the string itself is simple. Equivalent to:

```
(simple-vector lw:simple-char length)
```

See also `text-string`

## **simple-text-string-p** *Function*

Summary Tests if an object is a simple text string.

Package `lispworks`

Signature `simple-text-string-p object => bool`

Arguments `object` The object to be tested.

Values `bool` `t` if `object` is a simple text string; `nil` otherwise.

Description This is the predicate for simple text strings.

See also `simple-text-string`

## **split-sequence** *Function*

Summary Returns a list of subsequences of a sequence, split at specified separator elements.

Package `lispworks`

Signature `split-sequence separator-bag sequence &key start end test key coalesce-separators -> sequences`

Arguments `separator-bag` A sequence.

|             |                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>sequence</i>            | A sequence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|             | <i>start, end</i>          | Bounding index designators for <i>sequence</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Description |                            | <p>The function <code>split-sequence</code> returns a list of subsequences of <i>sequence</i> (between start and end), split when an element in the sequence <i>separator-bag</i> is found. The structure of <i>sequence</i> is not changed and the elements matching <i>separator-bag</i> are not included in the resulting sequences.</p> <p>The function <i>test</i>, which defaults to <code>eq1</code>, is used to compare the elements of <i>sequence</i> and the elements of <i>separator-bag</i>.</p> <p>If true, the function <i>key</i> is applied to the elements of <i>sequence</i> before <i>test</i> is called.</p> <p>If <i>coalesce-separators</i> is true, then empty sequences are removed.</p> |

| Values      | <i>result</i>              | A list of sequences.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description |                            | <p>The function <code>split-sequence-if</code> returns a list of subsequences of <i>sequence</i> (between start and end), split by where the function <i>predicate</i> returns true for an element. The structure of <i>sequence</i> is not changed and the elements identified by the predicate are not included in the resulting sequences.</p> <p>If non-nil, the function <i>key</i> is applied to the elements of <i>sequence</i> before <i>predicate</i> is called.</p> <p>If <i>coalesce-separators</i> is true, then empty sequences are omitted from <i>result</i>.</p> |

|             |                            | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Values      | <i>result</i>              | A list of sequences.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description |                            | <p>The function <code>split-sequence-if-not</code> returns a list of subsequences of <i>sequence</i> (between start and end), split by where the function <i>predicate</i> returns false for an element. The structure of <i>sequence</i> is not changed and the elements identified by the predicate are not included in the resulting sequences.</p> <p>If non-nil, the function <i>key</i> is applied to the elements of <i>sequence</i> before <i>predicate</i> is called.</p> <p>If <i>coalesce-separators</i> is true, then empty sequences are omitted from <i>result</i>.</p> |

|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>start-tty-listener</code> returns a process that runs a listener read-eval-print loop connected to <code>*terminal-io*</code>.</p> <p>If <code>force</code> is <code>nil</code>, then <code>start-tty-listener</code> checks if the default listener process is alive or if there is a live process with name "TTY Listener". If such a process exists, <code>start-tty-listener</code> simply returns <code>nil</code> and does not start a new process. If no such process exists, or if <code>force</code> was <code>t</code>, then <code>start-tty-listener</code> starts a new listener process named "TTY Listener", and returns it.</p> <p>If a REPL with I/O through <code>*terminal-io*</code> (such as a REPL started by <code>start-tty-listener</code>) is in the debugger, then by default it blocks multiprocessing. This behavior is controlled by the value of <code>*terminal-debugger-block-multiprocessing*</code>.</p> |

## **string-append** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| Summary     | Constructs a single string from a number of strings.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                              |
| Package     | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                              |
| Signature   | <code>string-append &amp;rest strings =&gt; string</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                              |
| Arguments   | <code>strings</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Any number of strings or string designators. |
| Values      | <code>string</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | A string.                                    |
| Description | <p>The <code>string-append</code> function takes any number of string designators and constructs a single string from them.</p> <p>A string designator is a string, a symbol or a character object.</p> <p>Each of the elements of the <code>strings</code> argument are first coerced into a string using the <code>string</code> function if they are not already a string.</p> <p><code>string</code> is a string of the "widest" type amongst <code>strings</code>. That is, the constructed string is of the same type as the argument with the largest element type.</p> |                                              |
| Example     | <pre>(readtable-case *readtable*) =&gt; :UPCASE  (string-append "foo" 'bar) =&gt; "fooBAR"  (type-of   (string-append     (coerce "A" 'simple-base-string)     (coerce "A" 'simple-text-string)   ))) =&gt; SIMPLE-TEXT-STRING</pre>                                                                                                                                                                                                                                                                                                                                           |                                              |

| <b>text-string</b> | <i>Type</i>                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary            | The text string type.                                                                                                                                                                                                                                                                                                                                                      |
| Package            | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                                                     |
| Signature          | <code>text-string length</code>                                                                                                                                                                                                                                                                                                                                            |
| Arguments          | <code>length</code> The length of the string (or <code>*</code> , meaning any).                                                                                                                                                                                                                                                                                            |
| Description        | The type of strings that can hold any simple character, that is, <code>(vector lw:simple-char length)</code> . This is the string type that is guaranteed to always hold any character used in writing text (program text or natural language). It will not hold character objects which have non-null attributes.<br><br>It is equivalent to <code>16-bit-string</code> . |

|             | <i>Function</i>                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------|
| Summary     | Ignores its arguments and returns t.                                                                           |
| Package     | <code>lispworks</code>                                                                                         |
| Signature   | <code>true &amp;rest ignore =&gt; t</code>                                                                     |
| Arguments   | <code>ignore</code> All arguments are ignored.                                                                 |
| Values      | t                                                                                                              |
| Description | The function <code>true</code> ignores all its arguments and returns t. It is useful as a functional argument. |

|             | <i>Macro</i>                                                                                                                                                                                                                                                                                                                           |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Removes an action from a specified list.                                                                                                                                                                                                                                                                                               |
| Package     | <code>lispworks</code>                                                                                                                                                                                                                                                                                                                 |
| Signature   | <code>undefine-action name-or-list action-name =&gt;</code>                                                                                                                                                                                                                                                                            |
| Arguments   | <code>name-or-list</code> A list or action list object.<br><code>action-name</code> A general lisp object.                                                                                                                                                                                                                             |
| Description | The macro <code>undefine-action</code> removes the action specified by <code>action-name</code> from the action list specified by <code>name-or-list</code> . If the action specified by <code>action-name</code> does not exist, then this is handled according to the value of <code>*handle-missing-action-in-action-list*</code> . |

*name-or-list* is evaluated to give either a list UID (to be looked up in the global registry of lists) or an action list object. *action-name* is a UID (general lisp object, to be compared by `equalp`). It uniquely identifies this action within its list (as opposed to among all lists).

## **undefine-action-list** *Macro*

Summary      Removes a given defined action list.

Package      **lispworks**

Signature      **undefine-action-list *uid* =>**

Arguments      ***uid***                  A lisp object.

Values      None.

Description      The macro **undefine-action-list** flushes the specified list (and all its action-items). If the action-list specified by *uid* does not exist, then handling is controlled by the value of the variable **\*handle-missing-action-list\***.

See also      **define-action-list**

## **unicode-alpha-char-p** *Function*

Summary      Returns a value like `c1:alpha-char-p`, but using specified Unicode rules.

Package      **lispworks**

Signature      **unicode-alpha-char-p *char* &key *style* => *flag***

|             |                                                                                                                                                                                 |                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Arguments   | <i>char</i>                                                                                                                                                                     | A character           |
|             | <i>style</i>                                                                                                                                                                    | A keyword             |
| Values      | <i>flag</i>                                                                                                                                                                     | A generalized boolean |
| Description | The function <code>unicode-alpha-char-p</code> returns <i>flag</i> as true if <i>char</i> is an alphabetic character according to the Unicode rules specified by <i>style</i> . |                       |
|             | The current implementation only supports one style:<br><code>:general-category</code>                                                                                           |                       |
|             | Use Unicode's "general category" for <i>char</i> .                                                                                                                              |                       |

`unicode-both-case-p`

## **unicode-both-case-p** Function

Summary      Returns a value like `c1:both-case-p`, but using specified Unicode rules.

Package      `lispworks`

Signature      `unicode-both-case-p char &key style => flag`

Arguments      `char`            A character  
`style`          A keyword

Values      `flag`          A generalized boolean

Description      The function `unicode-both-case-p` returns `flag` as true if `char` has case according to the Unicode rules specified by `style`.

The current implementation only supports one style:

`:general-category`

Use Unicode's "general category" for *char*.

Notes      The name of `unicode-both-case-p` is slightly confusing, because it matches the ANSI Common Lisp definition "a character with case" whereas there is no guarantee that both cases actually exist. Note also that there are some "alpha" chars which are not lower or upper case.

`unicode-lower-case-p`  
`unicode-upper-case-p`

## **unicode-char-equal**

## **unicode-char-not-equal**

## *Functions*

Summary      Compares two characters, ignoring case using specified Unicode rules.

Package      **lispworks**

Signatures    **unicode-char-equal *char1* *char2* &key *style* => *flag***  
**unicode-char-not-equal *char1* *char2* &key *style* => *flag***

Arguments    *char1*      A character

*char2*      A character

*style*      A keyword

Values        *flag*      A generalized boolean

Description    The function **unicode-char-equal** returns true if the characters *char1* and *char2* are equal, and the function **unicode-char-not-equal** returns true if the characters *char1* and *char2* are not equal. Both functions ignore case using Unicode rules specified by *style*.

The current implementation only supports one style of comparison:

**:simple-case-fold**

                Compares characters using Unicode's simple case folding rules.

See also     **unicode-char-greaterp**

**unicode-char-greaterp****unicode-char-lessp***Functions*

**Summary**      Compares two characters, ignoring case using specified Unicode rules.

**Package**      **lispworks**

**Signatures**      **unicode-char-greaterp *char1 char2 &key style -> flag***  
**unicode-char-lessp *char1 char2 &key style -> flag***

**Arguments**      ***char1***      A character

***char2***      A character

***style***      A keyword

**Values**      ***flag***      A generalized boolean

**Description**      The functions **unicode-char-greaterp** and **unicode-char-lessp** return true if the character *char1* is greater than (or for **unicode-char-lessp**, less than) the character *char2*, similarly to **c1:char-greaterp** and **c1:char-lessp** but ignoring case using Unicode rules specified by *style*.

The current implementation only supports one style of comparison:

**:simple-case-fold**

                  Compares characters using Unicode's simple lowercase folding rules.

**See also**      **unicode-char-equal**

**unicode-char-not-greaterp**

*Function*

**Description**      The current implementation only supports one style of comparison:

**:simple-case-fold**

Compares characters using Unicode's simple case folding rules.

See also [unicode-char-equal](#)

## **unicode-char-not-greaterp**

## **unicode-char-not-lessp**

## *Functions*

Summary      Compares two characters, ignoring case using specified Unicode rules.

Package      **lispworks**

Signatures    **unicode-char-not-greaterp *char1 char2 &key style => flag***  
**unicode-char-not-lessp *char1 char2 &key style => flag***

Arguments    ***char1***      A character  
                ***char2***      A character  
                ***style***      A keyword

Values        ***flag***      A generalized boolean

Description    The functions **unicode-char-not-greaterp** and **unicode-char-not-lessp** return true if the character *char1* is not greater (or for **unicode-char-not-lessp**, not less) than the character *char2*, similarly to **cl:char-not-greaterp** and **cl:char-not-lessp** but ignoring case using Unicode rules specified by *style*.

The current implementation only supports one style of comparison:

**:simple-case-fold**

Compares characters using Unicode's simple lowercase folding rules.

## **unicode-string-greaterp**

## **unicode-string-lessp**

### *Functions*

**Summary**      Compares two strings, ignoring case using specified Unicode rules.

**Package**      **lispworks**

**Signatures**      **unicode-string-greaterp** *string1 string2 &key start1 start2 end1 end2 style => mismatch-index*

**unicode-string-lessp** *string1 string2 &key start1 start2 end1 end2 style => mismatch-index*

**Arguments**

|                     |                                              |
|---------------------|----------------------------------------------|
| <i>string1</i>      | A string designator                          |
| <i>string2</i>      | A string designator                          |
| <i>start1, end1</i> | Bounding index designators of <i>string1</i> |
| <i>start2, end2</i> | Bounding index designators of <i>string2</i> |
| <i>style</i>        | A keyword                                    |

**Values**      *mismatch-index* A bounding index of *string1* or **nil**

**Description**      The functions **unicode-string-greaterp** and **unicode-string-lessp** compare the designated substrings of *string1* and *string2*, similarly to **c1:string-greaterp** and **c1:string-greaterp** but ignoring case using Unicode rules specified by *style*. The values of *start1* and *start2* default to 0, while the values of *end1* and *end2* default to **nil**.

The value of *mismatch-index* is the index where the strings mismatch (as an offset from the beginning of *string1*) if *substring1* is greater (or for **unicode-string-lessp**, less) than *substring2*, or **nil** otherwise.

The current implementation only supports one style of comparison:

**:simple-case-fold**

Compares each character of the string using Unicode's simple lowercase folding rules.

See also      **unicode-string-equal**  
                 **unicode-string-not-greaterp**

Description     The current implementation only supports one style of comparison:

**:simple-case-fold**

Compares each character of the string using Unicode's simple case folding rules.

See also      **unicode-string-equal**

## **unicode-string-not-greaterp**

## **unicode-string-not-lessp**

## *Functions*

Summary     Compares two strings, ignoring case using specified Unicode rules.

Package     **lispworks**

Signatures    **unicode-string-not-greaterp *string1* *string2* &key *start1* *start2* *end1* *end2* *style* => *mismatch-index***

**unicode-string-not-lessp *string1* *string2* &key *start1* *start2* *end1* *end2* *style* => *mismatch-index***

Arguments    *string1*        A string designator  
                 *string2*        A string designator  
                 *start1*, *end1*    Bounding index designators of *string1*  
                 *start2*, *end2*    Bounding index designators of *string2*  
                 *style*          A keyword

Values        *mismatch-index*    A bounding index of *string1* or **nil**

| Arguments   | <p><i>path</i>            A string or a list of strings.</p> <p><i>value-name</i>      A string.</p> <p><i>product</i>        A keyword.</p>                                                                                                                                                                                                                            |                 |
| Values      | <p><i>value</i>          A Lisp object.</p> <p><i>valuep</i>         A boolean.</p>                                                                                                                                                                                                                                                                                     |                 |
| Description | The function <code>user-preference</code> reads the value of the registry entry <i>value-name</i> under <i>path</i> under the registry path defined for <i>product</i> by <code>(setf product-registry-path)</code> . If the registry entry was found a second value <i>t</i> is returned. If the registry entry was not found, then <i>value</i> is <code>nil</code> . |                 |

The function (`setf user-preference`) sets the value of that registry entry to *value*.

If *path* is a list of strings, then it is interpreted like the directory component of a pathname. If *path* is a string, then any directory separators should be appropriate for the platform - that is, use backslash on Windows, and forward slash on Unix/Linux/Mac OS X systems.

#### Notes

1. When *value* is a string, `user-preference` stores a print-escaped string in the registry and reads it back with `read-from-string`. Therefore it may not work with string values stored by other software.
2. While *product* can in principle be any Lisp object, values of *product* are compared by `eq`, so you should use keywords.
3. The CAPI provides a way to store window geometry - see the entry for `capi:top-level-interface-save-geometry-p` in the *LispWorks CAPI Reference Manual*.

#### Example

This example is on Microsoft Windows. Note the use of backslashes as directory separators in the *path* argument:

```
(setf (user-preference "My Stuff\\FAQ"
 "Ultimate Answer"
 :product :deep-thought)
 42)
=>
42
```

This is equivalent to the previous example, and is portable because we avoid the explicit directory separators in the *path* argument:

```
(setf (user-preference (list "My Stuff" "FAQ")
 "Ultimate Answer"
 :product :deep-thought)
 42)
=>
42
```

We can retrieve values on Windows like this:

```
(user-preference "My Stuff\\FAQ"
 "Ultimate Answer"
 :product :deep-thought)
=>
42
t
```

We can retrieve values on any platform like this:

```
(user-preference (list "My Stuff" "FAQ")
 "Ultimate Question"
 :product :deep-thought)
=>
nil
nil
```

| <i>form</i>      | A form, which must evaluate to non-nil.                                                                                                                                                                                                                                                                                        |                                                                   |                                                                   |             |                                         |             |                                                                             |  |
| <i>body</i>      | A body of code to be evaluated conditionally on the result of <i>form</i> .                                                                                                                                                                                                                                                    |                                                                   |                                                                   |             |                                         |             |                                                                             |  |
| Values           | <i>result</i>                                                                                                                                                                                                                                                                                                                  | The result of evaluating <i>body</i> using the value <i>var</i> . |                                                                   |             |                                         |             |                                                                             |  |

|             |                                                                                                                                                                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The macro <code>when-let*</code> expands into nested <code>when-let</code> forms. The bindings are evaluated in turn as long as each returns non-nil. If the last binding evaluates to non-nil, <i>body</i> is executed. Within the code <i>body</i> , each variable <i>var</i> is bound to the result of the corresponding form <i>form</i> . |
| Example     | <pre>(defmacro divisible (n &amp;rest divisors)   `(~(when-let* , (loop for div in divisors                          collect (list (gensym)                                        (zerop (mod n div))))))     t))</pre>                                                                                                                       |

| Arguments                              | <p><i>action-list-var</i> A variable.</p> <p><i>action-item-var</i> A variable.</p> <p><i>ignore-errors-p</i> A boolean.</p> <p><i>body</i> A body of Lisp code.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |              |
| Description                            | The <b>with-action-item-error-handling</b> macro executes the <i>body</i> with <i>action-list-var</i> and <i>action-item-var</i> are bound to the action list and item respectively. If <i>ignore-errors-p</i> is set to <b>t</b> then errors are handled. The behavior of the handler is to signal a warning in which the action-list, item and original error are all reported; execution then continues with the next action-item.                                                                                                                                                                                                     |              |
| Example                                | <pre>(defun my-execution-function (the-action-list                                other-args                                &amp;key ignore-errors-p                                &amp;allow-other-keys)   (with-action-list-mapping (the-action-list                             an-action-item                             action-item-data)     (with-action-item-error-handling (the-action-list                                       an-action-item                                       ignore-errors-p)       (do-something-interesting-first)       (apply (car action-item-data) other-args (cdr action-item-data)))))</pre> |              |
|                                        | If this function was invoked with the keyword argument<br><b>:ignore-errors-p t</b> , and an error was signalled while exe-                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |              |

cuting the body-form(s) for one of the action-items, then a warning such as:

```
Warning: Got an error 'The variable *PREV-STATE* is
unbound.' while executing action "Initialize State" in
list "Startup Inits".
```

would be signalled and execution would continue with the next action-item.

## **with-action-list-mapping** *Macro*

**Summary** Maps over an action list's actions with given variables bound to the executing action and its data.

**Package** `lispworks`

**Signature** `with-action-list-mapping action-list item-var data-var  
&optional post-process &body body`

**Arguments** `action-list` An action list.

`item-var` A Lisp symbol.

`data-var` A Lisp symbol.

`post-process` A keyword.

`body` A body of Lisp code.

**Description** The `with-action-list-mapping` macro maps over an action-list's action-items. During execution, the symbols specified for `item-var` and `data-var` are bound to the executing action-item and its data respectively. See `execute-actions` for more on post-processing.

If this function is invoked with the keyword argument `:post-process :collect`, a list the values returned by each action-item's setf operation are returned.

**Examples**

```
(defun my-execution-function
 (the-action-list other-args
 &key (post-process nil)
 &allow-other-keys)
 (declare (ignore other-args))
 (with-action-list-mapping (the-action-list
 an-action-item
 action-item-data
 post-process)
 (do-something-interesting-first)
 (setf (symbol-value (car action-item-data))
 (apply (cadr action-item-data)
 (cddr action-item-data)))))
```

**See also****execute-actions****with-unique-names***Macro*

**Summary** Returns a body of code with each specified name bound to a similar name.

**Package** **lispworks**

**Signature** **with-unique-names (&rest names) &body body => result**

**Arguments** **names** The names to be rebound in *body*.

**body** The body of code within which *names* are rebound.

**Values** **result** The result of evaluating *body*.

**Description** Returns the body with each *name* bound to a symbol of a similar name (compare **gensym**).

**Example** After defining

```
(defmacro lister (p q)
 (with-unique-names (x y)
 `(let ((,x (x-function))
 (,y (y-function)))
 (list ,p ,q ,x ,y))))
```

the form (**lister i j**) macroexpands to

```
(LET* ((#:X-88 (X-FUNCTION))
 (#:Y-89 (Y-FUNCTION)))
 (LIST i j #:X-88 #:Y-89))
```

## The MP Package

This chapter describes symbols available in the `mp` package, giving you access to the multiprocessing capabilities of LispWorks.

Multiprocessing is discussed in detail in Chapter 15, “Multiprocessing”.

|             |                                                                                                                                                    | <i>Macro</i>                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| Summary     | Allows control over blocking interrupts.                                                                                                           |                                                   |
| Package     | <code>mp</code>                                                                                                                                    |                                                   |
| Signature   | <code>allowing-block-interrupts start-blocked &amp;body body =&gt; results</code>                                                                  |                                                   |
| Arguments   | <code>start-blocked</code>                                                                                                                         | A generalized boolean                             |
|             | <code>body</code>                                                                                                                                  | Code                                              |
| Values      | <code>results</code>                                                                                                                               | Values returned by evaluating <code>body</code> . |
| Description | The macro <code>allowing-block-interrupts</code> executes <code>body</code> allowing control over blocking interrupts by <code>current-pro-</code> |                                                   |

`process-unblock-interrupts` and `current-process-unblock-interrupts`.

Within the dynamic scope of `allowing-block-interrupts`, you can switch the blocking of interrupts on and off. Blocking interrupts prevents any interruption of the current process, including `process-interrupt`, `process-kill`, `process-reset`, `process-break` and `process-stop`. These interrupts are all queued and processed once interrupts become unblocked.

Blocking interrupts also blocks interrupts due to UNIX interrupts. Such interrupts are processed either by another Lisp thread, or once interrupts become unblocked.

If `start-blocked` is true, `allowing-block-interrupts` blocks interrupts on entry. If `start-blocked` is false, the state does not change on entry. If you want to ensure that the initial forms of `allowing-block-interrupts` are interruptible even if it is inside the scope of another `allowing-block-interrupts`, you need to explicitly call `current-process-unblock-interrupts` on entry.

`allowing-block-interrupts` can be used recursively.

In compiled code, `allowing-block-interrupts` with a true value of the `start-blocked` argument is guaranteed not to process interrupts before an explicit change to the blocking state (that includes exiting the scope of `allowing-block-interrupts`). In particular, if the first cleanup form of an `unwind-protect` is a call to `allowing-block-interrupts`, it is guaranteed to execute without interrupts on exit from the protected form. No such guarantee is given in interpreted code.

On exit from `allowing-block-interrupts`, the current state of interrupt blocking and whether there is a surrounding use of `allowing-block-interrupts` OR with-interrupts-blocked is restored to the state that existed on entry.

`allowing-block-interrupts` returns the results of `body`.

## **any-other-process-non-internal-server-p**

## *Function*

**Summary** Tests whether there is any other process except the caller that is not marked as "internal server".

## Package mp

Signature any-other-process-non-internal-server-p => result

Arguments      None.

Values              *result*              A boolean.

Description The function `any-other-process-non-internal-server-p` is the predicate for whether there is any other process, except the caller process, that is not marked as "internal server".

**Notes** Processes are marked as "internal server" by a true value for `:internal-server` amongst the *keywords* in a call to `process-run-function`.

| Values      | <i>result</i>  | An integer, a symbol or a <code>mp:process</code> object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Description |                | <p>The function <code>barrier-block-and-wait</code> enables the barrier <i>barrier</i> with <i>t</i>, that is it makes any number of arrivers wait, and then waits until <i>count</i> arrivers arrive.</p> <p><i>wait-if-used-p</i> controls whether to wait if another process is already inside <code>barrier-block-and-wait</code>. The default value of <i>wait-if-used-p</i> is <code>nil</code>.</p> <p><i>barrier</i> is a barrier object made by <code>make-barrier</code>.</p> <p><i>errorp</i> controls whether to signal an error if another process is already inside <code>barrier-block-and-wait</code> and <i>wait-if-used-p</i> is <code>nil</code>. The default value of <i>errorp</i> is <code>nil</code>.</p> <p><i>timeout</i>, if non-<code>nil</code>, specifies the time in seconds to wait before timing out. The default value of <i>timeout</i> is <code>nil</code>.</p> <p><i>unlock</i> specifies whether processes that already wait on the barrier should be unblocked first. The default value of <i>unlock</i> is <code>nil</code>.</p> <p><code>barrier-block-and-wait</code> is "using" the barrier, and only one process can do it the same time. <code>barrier-block-and-wait</code> first tries to mark the barrier as used by the current process. It will fail if another process is inside <code>barrier-block-and-wait</code> with the same barrier. In this case it does one of three options:</p> <ol style="list-style-type: none"> <li>1. By default, it returns the other process.</li> <li>2. If <i>wait-if-used-p</i> is non-<code>nil</code>, it calls <code>barrier-wait</code> on the barrier <i>barrier</i> (without any keyword argument) and returns the result.</li> <li>3. If <i>errorp</i> is non-<code>nil</code>, it calls <code>error</code>.</li> </ol> |

Once `barrier-block-and-wait` has successfully marked `barrier` as used, it changes its count to `t` as if by calling `(barrier-change-count barrier t)`, which will cause other `barrier-wait` calls to wait. If `unlock` is non-nil, it first unblocks all processes that wait on the barrier, so the effect is the same as `(barrier-enable barrier t)`.

It then waits until the arriver count of the barrier is equal or bigger than `count`, or, if `timeout` is supplied, `timeout` seconds passed. It then returns the number of arrivers.

`result` can be one of three types:

|                         |                                                                                                                                                                                        |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>integer</code>    | The call was successful, and <code>result</code> is the number of arrivers.                                                                                                            |
| <code>symbol</code>     | <code>barrier</code> was in use, and <code>wait-if-used-p</code> is non-nil, so <code>barrier-wait</code> was called. <code>result</code> is the result of <code>barrier-wait</code> . |
| <code>mp:process</code> | <code>barrier</code> is in use, and <code>result</code> is the process that uses it.                                                                                                   |

## Notes

1. When `barrier-block-and-wait` returns the barrier is still set with `t`, that is calls to `barrier-wait` on barrier will wait. Normally the current process will go on to do some operations that require the other processes to wait, and then release them by calling `barrier-disable` or `barrier-enable`.
2. In typical usage, the arriver count is just increased by one by each call to `barrier-wait`, so as long as other processes use only `barrier-wait` (or `barrier-block-and-wait` with `wait-if-used-p` non-nil), `barrier-block-and-wait` will return after `count` processes called `barrier-wait` and are waiting. That is the intention of `barrier-block-and-wait`. If other processes call functions that manipulate the arriver count or the count (`barrier-disable`, `barrier-enable`, `barrier-unblock`, `barrier-`

`change-count`), then `barrier-block-and-wait` will "get confused", in the sense that while its behavior is still well-defined, it is not intuitive.

3. With the default keyword values (maybe with `timeout`), `barrier-block-and-wait` is useful for controlling a fixed set of processes by another "master" process. The processes in the set need to call `barrier-wait` at appropriate points. When the "master" process wants to stop them for a while, it calls `barrier-block-and-wait`. When it wants to restart them, it calls `barrier-disable`.
4. The argument `wait-if-used-p` is useful when any member of a group of processes may decide that it needs to stop all the other processes in the group. In this case, this process will call `barrier-block-and-wait` with `wait-if-used-p` non-nil (and count the number of processes in the group minus one). If two of the processes happen to call it at the same time, one will get the barrier, and the other process will have to wait.
5. The effect of `barrier-block-and-wait` can be approximated by using `barrier-change-count` followed by normal `process-wait` that checks the arrivers count in the wait function. `barrier-block-and-wait` has two advantages:
  - a) It checks against more than one process trying to do it at the same time.
  - b) `barrier-block-and-wait` will wake up immediately when the arriver count reaches the right number. `process-wait` will wake up only when the scheduler checks the wait function and wakes it up.

| <i>reset-count</i>  | A positive fixnum, <code>t</code> or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |            |                    |                                                         |                     |            |
| <i>kill-waiting</i> | A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                |            |                    |                                                         |                     |            |
| Description         | <p>The function <code>barrier-unblock</code> unblocks the barrier <code>barrier</code>, potentially disabling it, resetting its count or killing the waiting processes.</p> <p>Without keyword arguments, <code>barrier-unblock</code> unblocks the barrier, which means that any thread that is waiting on the barrier wakes and returns from <code>barrier-wait</code>, and the arriver count is reset to 0.</p> <p>If <code>disable</code> is true, or if <code>disable</code> is not passed and the barrier was made with <code>disable-on-unblock</code> true, then <code>barrier-unblock</code> also disables the barrier, so any further calls to <code>barrier-wait</code> return <code>nil</code> immediately.</p> <p>If <code>reset-count</code> is true, it must be valid count (a positive fixnum or <code>t</code>), and <code>barrier-unblock</code> sets the count of the barrier to this value.</p> <p>If <code>kill-waiting</code> is true, instead of waking up the waiting threads, <code>barrier-unblock</code> kills them (by <code>process-kill</code>).</p> |                |            |                    |                                                         |                     |            |

| Description | <p>The function <code>barrier-wait</code> waits on a barrier until enough threads arrive. When <code>barrier-wait</code> is called it "arrives", and when the number of arrivers reaches the count of the barrier (that is, the <code>count</code> argument to <code>make-barrier</code>), <code>barrier-wait</code> returns. Effectively, the last "arriver" unblocks the barrier and wakes up all the other waiting threads.</p> <p><i>timeout</i> is the maximum time to wait in seconds.</p> <p>If <i>pass-through</i> is true, it does not actually wait.</p> <p><i>discount-on-abort</i> controls whether to change the arrivers count on an abort.</p> |

*discount-on-timeout* controls whether to change the arrivers count on a timeout.

*disable-on-unblock* controls whether to disable the barrier when unblocking.

*callback*, if supplied, specifies a callback called before unblocking.

`barrier-wait` first checks if the barrier is disabled, and if it is `barrier-wait` returns `nil` immediately. It then checks the number of arrivers, which is the number of other calls to `barrier-wait` on the same barrier since it was last unblocked or created.

If the number of arrivers is less than the count minus 1, `barrier-wait` increases the number of arrivers, and then waits for the barrier to be unblocked (unless *pass-through* is true). If the number of arrivers is the count minus 1, `barrier-wait` unblocks the barrier (described below) and returns `:unblocked`.

*discount-on-abort*, *discount-on-timeout*, *disable-on-unblock* and *callback* allow you to control the waiting and also the unblocking of the barrier. For each of these, the effective value is either that supplied to `barrier-wait`, or if it was not supplied to `barrier-wait`, the value in the barrier itself (see `make-barrier`).

*timeout* can be used to limit the time that `barrier-wait` waits. It is either a number of seconds or `nil`, meaning no timeout. If `barrier-wait` times out, it returns `:timeout`. By default it does not change the number of arrivers after a timeout, so the call is still counted as an "arrival", but this can be changed by using *discount-on-timeout*. If *discount-on-timeout* is true then after a timeout `barrier-wait` decrements the arrivers count, so the call has no overall effect on the arrivers count.

If `barrier-wait` is aborted while it waits (for example by `process-kill` or throwing using `process-interrupt`), by

default it does not change the arrivers count, so the call still counts as an arrival, but this can be changed by using *discount-on-abort*. If *discount-on-abort* is true, then on aborting **barrier-wait** decrements the arrivers count, so the call has no overall effect on the arrivers count.

If **barrier-wait** would have waited but *pass-through* is true, it returns the symbol `:passed-through` instead of waiting. Hence a call to **barrier-wait** with a true value of *pass-through* has the effect of incrementing the arriver count, and unblocking other waiters if needed, but never itself waiting.

Unblocking the barrier: when the number of arrivers is the count of the barrier minus 1, **barrier-wait** "unblocks the barrier". This involves the following steps:

1. If *callback* is true it is called with the barrier while holding an internal lock on the barrier. See the comment in `make-barrier`. If the callback aborts, nothing has been changed in the barrier (including no change to the arrivers).
2. The barrier is marked as unblocked for the currently waiting threads.
3. The number of arrivers in the barrier is reset to 0. Unless the next step disables the barrier, this means that any subsequent call to **barrier-wait** will wait, as if the barrier had just been created.
4. If *disable-on-unblock* is true, **barrier-wait** then disables the barrier. That means that until it is enabled, any call to **barrier-wait** will return immediately.
5. It wakes up all the waiting threads.
6. It returns the symbol `:unblocked`.

The possible values of *result* occur in these circumstances:

- t** The current process waited and some other process unblocked the barrier.

|                              |                                                    |
|------------------------------|----------------------------------------------------|
| <code>:unblocked</code>      | The current process unblocked the barrier.         |
| <code>:timeout</code>        | The wait timed out.                                |
| <code>:passed-through</code> | Pass through because <i>pass-through</i> was true. |
| <code>nil</code>             | The barrier is disabled.                           |

|          |                                                                                                                                                                                                                                                                                                                                            |

| Description |                         | <p>The function <code>condition-variable-broadcast</code> wakes all threads currently waiting on the condition variable <code>condvar</code>. In most uses of condition variables, the caller should be holding the lock that the waiter used when calling <code>condition-variable-wait</code> for this condition variable, but this is not required. When using the lock, you may prefer to use <code>lock-and-condition-variable-broadcast</code>.</p> <p>The return value <code>signalledp</code> is non-nil if some processes were signalled, or <code>nil</code> if there were no processes waiting.</p> |

| Description | <p>The function <code>condition-variable-signal</code> wakes exactly one thread waiting on the condition variable <code>condvar</code>. In most uses of condition variables, the caller should be holding the lock that the waiter used when calling <code>condition-variable-wait</code> for this condition variable, but this is not required. When using the lock, you may prefer to use <code>lock-and-condition-variable-signal</code>.</p> <p>The return value <code>signalledp</code> is non-nil if a process was signalled, or <code>nil</code> if there were no processes waiting.</p> |                       |

| Description |                    | <p>The function <code>condition-variable-wait</code> waits at most <i>timeout</i> seconds for the condition variable <i>condvar</i> to be signalled. The lock <i>lock</i> is released while waiting and claimed again before returning. The caller must be holding the lock <i>lock</i> before calling this function.</p> <p>The return value <i>wakep</i> is non-nil if the signal was received or nil if there was a timeout. If <i>timeout</i> is nil, <code>condition-variable-wait</code> waits indefinitely.</p> <p>If <i>wait-reason</i> is non-nil, it is used as the <i>wait-reason</i> while waiting for the signal.</p> <p>It is recommended that you use <code>lock-and-condition-variable-wait</code> or <code>simple-lock-and-condition-variable-wait</code> instead of <code>condition-variable-wait</code>. The locking functions make it easier to avoid mistakes, and can be more efficient.</p> |
| Notes       |                    | <i>timeout</i> controls how long to wait for the signal: before returning, the function waits to claim the lock, possibly indefinitely.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Description | <p>The function <code>current-process-block-interrupts</code> blocks interrupts in the current process.</p> <p>It signals an error if called outside the dynamic scope of <code>allowing-block-interrupts</code> or <code>with-interrupts-blocked</code>.</p> <p>Blocking interrupts prevents any interruption of the current process, including <code>process-interrupt</code>, <code>process-kill</code>, <code>process-reset</code>, <code>process-break</code> and <code>process-stop</code>. These interrupts are all queued and processed once interrupts become unblocked.</p> <p>Blocking interrupts also blocks interrupts due to UNIX interrupts. Such interrupts are processed either by another Lisp thread, or once interrupts become unblocked.</p> <p>The effect of <code>current-process-block-interrupts</code> stays in force until the next call to either <code>current-process-unblock-interrupts</code> or <code>current-process-block-interrupts</code>, or an exit out of the scope of a surrounding <code>allowing-block-interrupts</code> or <code>with-interrupts-blocked</code>. Inside this range bodies of <code>allowing-block-interrupts</code> and <code>with-interrupts-blocked</code> have their own state, but they restore it on exit.</p> |

| Arguments                    | <i>time</i>     | A positive number                                                                                                                                                                                                 |
|                              | <i>function</i> | A function designator.                                                                                                                                                                                            |
|                              | <i>args</i>     | Arguments passed to <i>function</i> .                                                                                                                                                                             |
| Values                       |                 | The keyword <code>:poked</code> , or <code>nil</code> .                                                                                                                                                           |
| Description                  |                 | The function <code>current-process-pause</code> sleeps for <i>time</i> seconds, but wakes up if another process did something to wake up the current process (normally this is <code>process-poke</code> , but it |

can also be `process-interrupt`, `process-stop`, `process-unstop` or `process-kill`).

`current-process-pause` is quite similar to `cl:sleep`, but it returns if anything causes the process to wake up, even if the time did not pass.

If *function* is passed just before going to sleep, `current-process-pause` applies *function* to *args*, and if this returns a true value `current-process-pause` returns it immediately.

*function* and *args* are not used otherwise. If another process calls `process-poke` on the current process after setting something that causes *function* to return true, it guarantees that `current-process-pause` will return immediately without sleeping.

If another process woke up the current process, `current-process-pause` returns the keyword `:poked`. If it slept the full time, it returns `nil`.

#### Notes

1. In contrast to `process-wait`, the *function* argument to `current-process-pause` is applied only once, and within the dynamic scope of `current-process-pause`. It therefore does not have any of the restrictions that the *wait-function* of `process-wait` has.
2. The purpose of *function* is to guard against the possibility that another process pokes the current process while it is in the process of going to sleep.
3. There is no way to distinguish between the function returning `:poked` and the process being poked in some way.

#### Example

Supposed you want to have a process that each minute does some cleanup, but may also be told by other processes to go and do the cleanup. The process be doing:

```
(loop
 (mp:current-process-pause 60 'check-for-need-cleanup)
 (do-cleanup))
```

Another process which wants to provoke a cleanup will do:

```
(setup-cleanup-flag)

(mp:process-poke *cleanup-process*)
```

Note that `check-for-need-cleanup` is passed to `current-process-pause`, because another process may call `process-poke` after `current-process-pause` was called but before it went to sleep. If `check-for-need-cleanup` was not passed, `current-process-pause` would unnecessarily sleep the whole 60 seconds in this case. The same thing could be implemented by `process-wait-with-timeout`, but the implementation above does not require a wait function that can run in another dynamic scope repeatedly at arbitrary times, and it uses much less system resources. It is also easier to debug.

## debug-other-process *Function*

Summary      Examine the stack of a process other than the current process.

Package      `mp`

Signature     `debug-other-process process`

Arguments    `process`      A process or a string.

Description    The function `debug-other-process` causes the debugger to be entered to examine the stack of another process *process*. The debugger itself continues to run in the current process, and the execution of the other process *process* is not affected. That means that all debugger commands that try to affect execution (for example `:a`, `:c`, `:res`, `:ret`, `:trap`) do not work as in the normal debugger. `:a` is changed instead to exit the debugger.

**Note:** if the other process is still active, the stack will change "under the feet" of the debugger, with unpredictable results. Thus `debug-other-process` is useful only for debugging purposes, or when you already stopped the other process.

The usual way to enter a debugger on another thread is to use `process-break`. However, that would fail if the other process hangs for some reason. In this situation, you can use `debug-other-process` to try to find out why it hangs.

If *process* is a string, the process is found as if by `find-process-from-name`. The list of process names can be found via `ps`.

                  `process-break`  
                  `ps`

### **\*default-process-priority\*** *Variable*

Summary      The default priority for processes.

Package      `mp`

Description      The variable `*default-process-priority*` contains the default priority for processes.

See also      `process-run-function`

### **ensure-process-cleanup** *Function*

Summary      Run forms when a given process terminates.

Package      `mp`

Signature      `ensure-process-cleanup cleanup-form &optional process =>`

Arguments      `cleanup-form`      Form to run when *process* terminates.  
                  `process`      The process to watch for termination. By default, this is the value of `*current-process*`.

Values      None.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | Ensures that the <i>cleanup-form</i> is present for the given process. When the process terminates, its cleanup forms are run. Cleanup forms can be functions of one argument (the process), or lists, in which case the <code>cadr</code> is applied to the process and the <code>cdr</code> of the list.<br><br>When adding cleanup forms, this function uses <code>equal</code> to ensure that the form is only added once. |
| Notes       | You can test for whether the current process is executing its cleanups with <code>current-process-in-cleanup-p</code> .                                                                                                                                                                                                                                                                                                        |
| Example     | A process calls <code>add-process-dependent</code> each time a dependent object is added to a process. When the process terminates, <code>inform-dependent-of-dead-process</code> is called on all dependent objects.                                                                                                                                                                                                          |
|             | <pre>(defun add-process-dependent (dependent)   (mp:ensure-process-cleanup    ` (delete-process-dependent ,dependent)))  (defun delete-process-dependent (process dependent)   (inform-dependent-of-dead-process dependent process))</pre>                                                                                                                                                                                     |
| See also    | <code>current-process-in-cleanup-p</code><br><code>process-kill</code>                                                                                                                                                                                                                                                                                                                                                         |

## find-process-from-name *Function*

|           |                                                                             |
|-----------|-----------------------------------------------------------------------------|
| Summary   | Finds a process from its name.                                              |
| Package   | <code>mp</code>                                                             |
| Signature | <code>find-process-from-name <i>process-name</i> =&gt; <i>result</i></code> |
| Arguments | <code>process-name</code> A string.                                         |
| Values    | <code>result</code> A <code>mp:process</code> , or <code>nil</code> .       |

|             |                                                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>find-process-from-name</code> returns the process with the name <i>process-name</i> .<br><br>If there is no such process, the function returns <code>nil</code> . |
| Example     | <pre>CL-USER 16 &gt; (mp:find-process-from-name "Listener 1") #&lt;MP:PROCESS Name "Listener 1" Priority 600000 State "Running"&gt;</pre>                                            |
| See also    | <code>get-process</code>                                                                                                                                                             |

## general-handle-event *Generic function*

|             |                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | "handles" an event, depending on the type of the event object.                                                                                         |
| Package     | <code>mp</code>                                                                                                                                        |
| Signature   | <code>general-handle-event event-object</code>                                                                                                         |
| Arguments   | <code>event-object</code> A Lisp object.                                                                                                               |
| Description | The generic function <code>general-handle-event</code> "handles" the <i>event-object</i> . What this actually means depends on the type of the object. |

There are system defined methods for these classes:

|                       |                                                      |
|-----------------------|------------------------------------------------------|
| <code>list</code>     | Apply the <code>car</code> to the <code>cdr</code> . |
| <code>function</code> | Call it.                                             |
| <code>symbol</code>   | If fbound call it, otherwise do nothing.             |
| <code>t</code>        | Do nothing.                                          |

You can add methods for your own classes.

`general-handle-event` is used by all functions that process events, for example `wait-processing-events` and `process-all-events`, as well as by internal waiting functions.

See also **`process-all-events`**

## **get-current-process**

*Function*

Summary Returns the current Lisp process.

Package **`mp`**

Signature **`get-current-process => result`**

Values *result* A **`mp:process`**, or **`nil`**.

Description The function **`get-current-process`** returns the actual process in which it is called. In this respect it differs from **`*current-process*`**, which can be bound to another process. In particular, when a process A calls the *wait-function* of process B, in the *wait-function* **`get-current-process`** returns the process A, but **`*current-process*`** is bound to process B.  
*result* is **`nil`** if multiprocessing is off.

See also **`*current-process*`**

## **get-process**

*Function*

Summary Returns a process corresponding to a supplied designator.

Package **`mp`**

Signature **`get-process process-designator => process`**

Arguments *process-designator*

A **`mp:process`**, a string, a stack-group, a function, a symbol or a fixnum.

|             |                         |                                                                                                                                                                            |
|-------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <i>process</i>          | A <code>mp:process</code> .                                                                                                                                                |
| Description |                         | The function <code>get-process</code> returns a process according to the supplied <i>process-designator</i> , which is interpreted as follows:                             |
|             | <code>mp:process</code> | Return it.                                                                                                                                                                 |
|             | A string                | Find the first process (highest priority) with matching name. Process names are compared by <code>string=</code> .                                                         |
|             | A stack-group           | Return the process of the stack-group.                                                                                                                                     |
|             | A function              | Return the first process that has <i>process-designator</i> as its function (that is, the third argument of <code>process-run-function</code> ).                           |
|             | A symbol                | First search for a process using the symbol name as a string, and (if that fails) then search using the symbol as a function.                                              |
|             | A fixnum                | Find a process for which <i>process-designator</i> is its unique id. The unique id of the current process can be found by<br><code>(sys:current-thread-unique-id)</code> . |
|             |                         | <i>result</i> is <code>nil</code> if multiprocessing is off.                                                                                                               |
| See also    |                         | <code>find-process-from-name</code>                                                                                                                                        |

## **get-process-private-property** *Function*

|           |                                               |                                                                                                                            |
|-----------|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Summary   | Gets the value of a process private property. |                                                                                                                            |
| Package   | <code>mp</code>                               |                                                                                                                            |
| Signature |                                               | <code>get-process-private-property <i>indicator</i> <i>process</i> &amp;optional <i>default</i> =&gt; <i>result</i></code> |
| Arguments | <i>indicator</i>                              | A Lisp object.                                                                                                             |

|             |                |                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>process</i> | A process.                                                                                                                                                                                                                                                                                                                                                       |
|             | <i>default</i> | A Lisp object.                                                                                                                                                                                                                                                                                                                                                   |
| Values      | <i>result</i>  | A property value, or <i>default</i> .                                                                                                                                                                                                                                                                                                                            |
| Description |                | The function <code>get-process-private-property</code> gets the value associated with <i>indicator</i> in the private properties of the process <i>process</i> . If there is no such property, the value <i>default</i> is returned.<br><br><code>get-process-private-property</code> can be used to read the values of private properties from another process. |
|             |                | The default value of <i>default</i> is <code>nil</code> .                                                                                                                                                                                                                                                                                                        |
| See also    |                | <code>process-private-property</code><br><code>remove-process-private-property</code><br><code>pushnew-to-process-private-property</code><br><code>remove-from-process-private-property</code>                                                                                                                                                                   |

|           |                          | <i>Function</i>                                                               |
|-----------|--------------------------|-------------------------------------------------------------------------------|
| Summary   |                          | Initializes multiprocessing before use.                                       |
| Package   |                          | <code>mp</code>                                                               |
| Signature |                          | <code>initialize-multiprocessing &amp;rest main-process-args =&gt; nil</code> |
| Arguments | <i>main-process-args</i> | A set of arguments for <code>process-run-function</code> .                    |
| Values    |                          | Returns <code>nil</code> .                                                    |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>initialize-multiprocessing</code> initializes multiprocessing, and it does not return until multiprocessing is finished.</p> <p><code>initialize-multiprocessing</code> applies the function <code>process-run-function</code> to each of the entries in <code>*initial-processes*</code> to create the initial processes.</p> <p>When called with <code>main-process-args</code>, it creates a <code>mp:process</code> object for the initial thread using the arguments in that list as if in the call</p> <pre>(apply 'mp:process-run-function main-process-args)</pre> <p>Supplying <code>main-process-args</code> is useful on Mac OS X if you want to run a pure Cocoa application, since the main thread needs to run the Cocoa event loop.</p> <p>It is not necessary to call <code>initialize-multiprocessing</code> when the LispWorks IDE is running (that is, after <code>env:start-environment</code> has been called), as this automatically starts up multiprocessing.</p> |
| Notes       | On Microsoft Windows, Linux, x86/x64 Solaris, FreeBSD and Mac OS X (using the Cocoa image), the LispWorks IDE starts up by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## **\*initial-processes\*** *Variable*

|             |                                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------|
| Summary     | A list of the processes the system initializes on startup.                                                     |
| Package     | <code>mp</code>                                                                                                |
| Description | The variable <code>*initial-processes*</code> specifies the processes which the system initializes on startup. |

Each element of the `*initial-processes*` list is a set of arguments for `process-run-function`.

Example To create a listener process as well as your own processes, evaluate this form before saving your image:

```
(push mp::*default-listener-process*
 mp::*initial-processes*)
```

| Values      | <code>result</code> <code>t</code> or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description | <p>The function <code>last-callback-on-thread</code> informs LispWorks that there are probably not going to be more callbacks from foreign code on the current thread (but does not guarantee this).</p> <p><code>last-callback-on-thread</code> must be used in the scope of a call into LispWorks by a foreign callable on a thread that was not created by LispWorks. It informs LispWorks that there are unlikely to be more callbacks into Lisp on the current thread. As a result, LispWorks can cleanup its side.</p> <p>For each thread that was not created by Lisp and on which there was a call into Lisp, LispWorks keeps data on the Lisp side which it uses to make the entry faster. If the thread goes away, this data is not needed and so LispWorks can free it.</p> |

If another callback occurs on the same thread after a callback that called `last-callback-on-thread`, LispWorks will have to recreate its side, which takes a little more time, but otherwise it works in the same way. Thus it is possible to call `last-callback-on-thread` even when it is not guaranteed that there will not be further callbacks on the same thread.

Calling `last-callback-on-thread` on a thread that was created by LispWorks has no effect.

`last-callback-on-thread` returns `t` when called on a thread that was not created by LispWorks, otherwise it returns `nil`.

|                           | <i>Function</i>                                                              |
|---------------------------|------------------------------------------------------------------------------|
| <b>list-all-processes</b> |                                                                              |
| Summary                   | Lists all the Lisp processes currently in the system.                        |
| Package                   | <code>mp</code>                                                              |
| Signature                 | <code>list-all-processes =&gt; process-list</code>                           |
| Arguments                 | None.                                                                        |
| Values                    | <code>process-list</code> A list of all the currently active Lisp processes. |
| Description               | Returns a list of all the active Lisp processes in LispWorks.                |

Example

```
CL-USER 71 > (pprint (mp:list-all-processes))

| Summary                               | Locks, applies a setup function, calls <b>condition-variable-broadcast</b> and unlocks.                                                                                                                                                                                                                                                                                                  |
| Package                               | <b>mp</b>                                                                                                                                                                                                                                                                                                                                                                                |
| Signature                             | <b>lock-and-condition-variable-broadcast lock condvar lock-timeout setup-function &amp;rest args</b>                                                                                                                                                                                                                                                                                     |
| Description                           | The function <b>lock-and-condition-variable-broadcast</b> locks the lock <i>lock</i> , applies the function <i>setup-function</i> , calls <b>condition-variable-broadcast</b> and unlocks. <b>lock-and-condition-variable-broadcast</b> makes it easier to avoid mistakes in using a condition variable.<br><br><b>lock-and-condition-variable-broadcast</b> performs the equivalent of: |

```
(mp:with-lock (lock nil lock-timeout)
 (apply setup-function args)
 (mp:condition-variable-broadcast condvar))
```

It returns the result of the call to `condition-variable-broadcast`.

See `condition-variable-broadcast` and `with-lock` for more details.

**Notes** `setup-function` is called with the lock held, so it should do the minimum amount of work and avoid locking other locks.

| <b>Summary</b>                            | Locks, applies a setup function, calls <code>condition-variable-signal</code> and unlocks.                                                                                                                                                                                                                                                                                                              |
| <b>Package</b>                            | <code>mp</code>                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Signature</b>                          | <code>lock-and-condition-variable-signal lock condvar lock-timeout setup-function &amp;rest args</code>                                                                                                                                                                                                                                                                                                 |
| <b>Description</b>                        | The function <code>lock-and-condition-variable-signal</code> locks the lock <code>lock</code> , applies the <code>setup-function</code> , calls <code>condition-variable-signal</code> and unlocks. <code>lock-and-condition-variable-signal</code> makes it easier to avoid mistakes in using a condition variable.<br><br><code>lock-and-condition-variable-signal</code> performs the equivalent of: |

```
(mp:with-lock (lock nil lock-timeout)
 (apply setup-function args)
 (mp:condition-variable-signal condvar))
```

It returns the result of the call to **condition-variable-signal**.

See **condition-variable-signal** and **with-lock** for more details.

|          |                                                                                                                                                                                                                                                                                                                                        |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <i>setup-function</i> is called with the lock held, so it should do the minimum amount of work and avoid locking other locks. Normally <i>setup-function</i> should only set the cell that the process(es) that wait(s) on the condition variable <i>condvar</i> check with the predicate in <b>lock-and-condition-variable-wait</b> . |
| See also | <b>lock-and-condition-variable-wait</b><br><b>simple-lock-and-condition-variable-wait</b><br><b>lock-and-condition-variable-broadcast</b><br><b>condition-variable-wait</b><br><b>condition-variable-signal</b><br><b>condition-variable-broadcast</b>                                                                                 |

|             | <i>Function</i>                                                                                                                                                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Locks a lock and calls a predicate. If this returns <b>nil</b> , performs the equivalent of <b>condition-variable-wait</b> . Optionally calls a function on return.                                                                                                 |
| Package     | <b>mp</b>                                                                                                                                                                                                                                                           |
| Signature   | <b>lock-and-condition-variable-wait</b> <i>lock</i> <i>condvar</i> <i>predicate</i><br><b>&amp;key</b> <i>args</i> <b>return-function</b> <b>return-function-args</b> <i>lock-timeout</i> <i>lock-wait-reason</i> <i>condvar-timeout</i> <i>condvar-wait-reason</i> |
| Description | The function <b>lock-and-condition-variable-wait</b> first locks the lock <i>lock</i> as in <b>with-lock</b> , using <i>lock-wait-reason</i> and                                                                                                                    |

`lock-timeout` for the `whostate` and `timeout` arguments of `with-lock`.

It then applies the function `predicate` to the arguments `args`. If this call returns `nil` it performs the equivalent of a call to `condition-variable-wait`, passing it the `condvar`, `lock`, `condvar-timeout` and `condvar-wait-reason`.

If `return-function` is supplied, it is then applied to `return-function-args`, and the return value(s) are returned.

Before returning, the lock is unlocked (in an unwinding form) as in `with-lock`.

`lock-and-condition-variable-wait` returns whatever `return-function` returns if it is supplied. If `return-function` is not supplied, `lock-and-condition-variable-wait` returns the result of the predicate if this is not `nil`, otherwise it returns the result of the equivalent call to `condition-variable-wait`.

#### Notes

1. `predicate` and the `return-function` are called with the lock held, so they should do as little as needed, and avoid locking anything else.
2. `lock-and-condition-variable-wait` makes it much easier to avoid errors when using condition variables.
3. When `return-function` is not supplied, `lock-and-condition-variable-wait` does not lock on return, which makes it much more efficient than the equivalent code using `with-lock` and `condition-variable-wait`.
4. When `return-function` is not needed, `simple-lock-and-condition-variable-wait` may be more convenient.
5. All the four signalling functions (`condition-variable-signal`, `condition-variable-broadcast`, `lock-and-condition-variable-signal`, `lock-and-condition-variable-broadcast`) can be used to wake a process

waiting in `lock-and-condition-variable-wait`. The non-locking one can be used without the lock when it is useful.

`condition-variable-broadcast`

## **lock-locked-p** *Function*

Summary The predicate for whether a lock is locked.

Package `mp`

Signature `lock-locked-p lock => result`

Arguments `lock` A lock.

Values `result` A boolean.

Description The function `lock-locked-p` is the predicate for whether a lock is locked. Since that can change at any time, the result is reliable only if you know that the state is not going to change.

If the lock is a "sharing" lock, this checks for an exclusive lock.

See also `make-lock`

## **lock-owned-by-current-process-p** *Function*

Summary Checks whether a lock is locked by the current thread.

|             |                                                                                                                                                                                                                                                                                                                                                                                  |

## **lock-recursively-locked-p** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | The predicate for whether a lock is recursively locked.                                                                                                                                                                                                                                                                                                                                                                                                   |  |
| Package     | <code>mp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |
| Signature   | <code>lock-recursively-locked-p lock =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                                                  |  |
| Arguments   | <code>lock</code> A lock.<br><code>result</code> A boolean.                                                                                                                                                                                                                                                                                                                                                                                               |  |
| Description | <p>The function <code>lock-recursively-locked-p</code> is the predicate for whether a lock is recursively locked. Since that can change at any time, the result is reliable only if you know that the state is not going to change. For the definition of recursive locking, see the <code>make-lock</code> argument <i>recursivelp</i>.</p> <p>If the lock is a "sharing" lock, <code>lock-recursively-locked-p</code> checks for an exclusive lock.</p> |  |
| See also    | <code>make-lock</code>                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |

## **lock-name** *Function*

|         |                             |
|---------|-----------------------------|
| Summary | Returns the name of a lock. |
| Package | <code>mp</code>             |

|             |                                                                                                                                                        |               |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Signature   | <code>lock-name lock =&gt; name</code>                                                                                                                 |               |
| Arguments   | <code>lock</code>                                                                                                                                      | A lock object |
| Values      | <code>name</code>                                                                                                                                      | A string      |
| Description | The function <code>lock-name</code> takes a lock object as its argument and returns the name of the lock object.                                       |               |
| Example     | <pre>(let ((lock (mp:make-lock :name "my lock")))   (mp:lock-name lock)) =&gt; "my lock"</pre>                                                         |               |

| Arguments         | <code>lock</code>                                                                                                                                                                                                                                                   | A lock object                                      |
| Values            | <code>result</code>                                                                                                                                                                                                                                                 | A process, <code>t</code> or <code>:unknown</code> |
| Description       | <p>The function <code>lock-owner</code> returns the process that currently owns the lock, or <code>nil</code>.</p> <p>If lock is a "sharing" lock then <code>lock-owner</code> checks for an exclusive lock (see <code>lock-owned-by-current-process-p</code>).</p> |                                                    |

If *lock* is locked then *result* is normally the process that locked it. If *lock* was locked while multiprocessing was not running then *result* is `t`. Also, if *lock* was locked by an unknown process (for example, the process is killed whilst holding the lock) then *result* is `:unknown`.

*result* is `nil` if *lock* is not locked.

Example

```
CL-USER 1 > (let ((lock (mp:make-lock :name
 "my lock")))
 (mp:lock-owner lock))
NIL

CL-USER 2 > (let ((lock (mp:make-lock :name
 "my lock")))
 (mp:with-lock (lock)
 (mp:lock-owner lock)))
#<MP:PROCESS Name "CAPI Execution Listener 1" Priority
0 State "Running">
```

## mailbox-count

## *Function*

Summary

Returns the number of objects currently in a mailbox.

Package

`mp`

Signature

`mailbox-count mailbox => count`

Arguments

`mailbox`

A mailbox.

Values

`count`

A non-negative integer.

|             |                                                                                                                                                                                                                                                 |

| Arguments   | <code>mailbox</code>                                    | A mailbox.                                                                                                                                                 |
| Values      | <code>result</code>                                     | Any object or <code>nil</code> .                                                                                                                           |
|             | <code>value-p</code>                                    | <code>t</code> or <code>nil</code> .                                                                                                                       |
| Description |                                                         | The function <code>mailbox-peek</code> returns the first object in the mailbox without removing it. If the mailbox is empty, <code>nil</code> is returned. |

If the mailbox *mailbox* is not empty, the function `mailbox-peek` returns the first object in the mailbox without removing it. The second returned value *value-p* is `t`.

If *mailbox* is empty, both return values *result* and *value-p* are `nil`.

- |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes | <ol style="list-style-type: none"> <li>1. Since another process may modify the mailbox at any point, the result is not necessarily the next object that the next call to <code>mailbox-read</code> will read, unless no other process is reading from the mailbox.</li> <li>2. <code>mailbox-peek</code> needs to lock the mailbox, which means it is significantly slower than <code>mailbox-not-empty-p</code>, and also may affect other processes. In most of the cases, <code>mailbox-not-empty-p</code> is sufficient and hence is preferable.</li> </ol> |

| Values      | <i>object</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | An object. |
|             | <i>flag</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | A boolean. |
| Description | The function <code>mailbox-read</code> returns the next object from the mailbox <i>mailbox</i> , or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                        |            |
|             | If <i>mailbox</i> is empty and <i>timeout</i> is <code>nil</code> , then <code>mailbox-read</code> blocks until an object is placed in <i>mailbox</i> . If <i>mailbox</i> is empty and <i>timeout</i> is a number, then <code>mailbox-read</code> blocks until an object is placed in <i>mailbox</i> or <i>timeout</i> seconds have passed. If the timeout occurs, then <code>mailbox-read</code> returns <code>nil</code> as the first value and also <i>flag</i> is <code>nil</code> . If an object is actually read from the mailbox, then <i>flag</i> is <code>t</code> . |            |
|             | The <i>wait-reason</i> argument defaults to " <code>Waiting for message in #&lt;Mailbox...&gt;</code> " and will be the value returned by <code>process-whostate</code> while <code>mailbox-read</code> is blocking.                                                                                                                                                                                                                                                                                                                                                          |            |
|             | The default value of <i>timeout</i> is <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |            |

|           |                                                           | <i>Function</i>                 |
|-----------|-----------------------------------------------------------|---------------------------------|
| Summary   | Returns the reader process of a mailbox.                  |                                 |
| Package   | <code>mp</code>                                           |                                 |
| Signature | <code>mailbox-reader-process mailbox =&gt; process</code> |                                 |
| Arguments | <i>mailbox</i>                                            | A mailbox.                      |
| Values    | <i>process</i>                                            | A process or <code>nil</code> . |

Description      The function `mailbox-reader-process` returns the reader process of *mailbox*.

## **mailbox-send** *Function*

Summary      Sends an object to a mailbox.

Package      `mp`

Signature      `mailbox-send mailbox object =>`

Arguments      *mailbox*      A mailbox  
                   *object*      An object

Description      The function `mailbox-send` sends *object* to *mailbox*. The object is queued in the mailbox for retrieval by the reader.

## **mailbox-wait-for-event** *Function*

Summary      Waits for an event in a "windowing friendly" way.

Package      `mp`

Signature      `mailbox-wait-for-event mailbox &key wait-reason wait-function process-other-messages-p no-hang-p stop-at-user-operation-p => event`

Arguments      *mailbox*      A mailbox.  
                   *wait-reason*      A string or `nil`.

| Description |                                 | <p>The function <code>mailbox-wait-for-event</code> waits for an event in a mailbox in a "windowing friendly" way. It reads an event from the mailbox <i>mailbox</i>. If there is no event in the mailbox, it waits for an event (unless <i>no-hang-p</i> is true).</p> <p>The value <i>event</i> is any object that was put in the mailbox, or <code>nil</code> if the mailbox is empty, possibly after waiting.</p> <p><code>mailbox-wait-for-event</code> is the appropriate way to wait for an event in a mailbox in an application with a graphical user interface, because it interacts correctly with the windowing system. Most importantly, on Microsoft Windows, when <i>process-other-messages-p</i> is true it processes Windows messages while it is waiting. The default value of <i>process-other-messages-p</i> is <code>t</code>.</p> <p><i>wait-function</i> is the wait function to be used, which is called with the mailbox <i>mailbox</i> as its argument. If <i>wait-function</i> is not supplied, a function that returns <code>t</code> when the mailbox is not empty is used internally.</p> <p><i>wait-reason</i> is used as the wait reason if it needs to wait. The default value of <i>wait-reason</i> is "Waiting for an event".</p> <p><i>process-other-messages-p</i> controls processing of other messages. On Microsoft Windows this means Windows messages. On other platforms it has no effect.</p> <p><i>no-hang-p</i> controls whether <code>mailbox-wait-for-event</code> should really wait. If <i>no-hang-p</i> is true and there is no event, it</p> |

returns immediately except on Microsoft Windows, where it may first process all Windows messages (depending on the value of *process-other-messages-p*). The default value of *no-hang-p* is `nil`.

*stop-at-user-operation-p* on Microsoft Windows causes `mailbox-wait-for-event` to return if it received a user operation message (meaning keyboard or mouse input). It has no effect on other platforms. The default value of *stop-at-user-operation-p* is `nil`.

If `mailbox-wait-for-event` is called when not Lisp is not multiprocessing, it returns immediately. The return value is an event or `nil`.

### **\*main-process\*** *Variable*

|             |                                                                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | The process associated with the main thread.                                                                                                                                                                                                     |
| Package     | <code>mp</code>                                                                                                                                                                                                                                  |
| Description | This special variable contains the process associated with the main thread of the application. On Mac OS X with the Cocoa GUI, this is the thread that runs the Cocoa event loop. On other platforms, this variable is always <code>nil</code> . |

### **make-barrier** *Function*

|         |                        |
|---------|------------------------|
| Summary | Returns a new barrier. |
| Package | <code>mp</code>        |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                       |

| Values      | <code>barrier</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | A barrier.                            |
| Description | <p>The function <code>make-barrier</code> returns a new barrier with count <code>count</code>.<br/> <code>count</code> can be <code>t</code>, which is interpreted as <code>most-positive-fixnum</code>.<br/> The barrier has the name <code>name</code>, which is useful for debugging but is not used otherwise. If <code>name</code> is omitted, then a default name is generated that is unique among all such default names.<br/> <code>discount-on-timeout</code> and <code>discount-on-abort</code> determine the default behavior when a thread times out or aborts while in the function <code>barrier-wait</code>. See the documentation for <code>barrier-wait</code>.<br/> If <code>disable-on-unblock</code> is true, then <code>barrier-wait</code> will disable the barrier by default when it unblocks it. See <code>disable-on-unblock</code> in the documentation for <code>barrier-wait</code>.<br/> <code>callback</code> is called by <code>barrier-wait</code> just before it unblocks the barrier. It is called with a single argument (the barrier) while holding an internal lock on the barrier that will prevent other operations on the barrier from running. The callback is guaranteed to happen before <code>barrier-wait</code> allows any of the other threads to continue.</p> |                                       |
| Notes       | Because the callback is called inside a lock, you should ensure that it is relatively short to prevent congestion if another thread tries to access the barrier. Allocating a few objects is reasonable. If there is a more expensive operation that has to be done by only one of the threads, it can be done                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                       |

by the thread that returned `:unblocked` from `barrier-wait`. The advantage of using the callback is that it is called before any of the waiting threads pass the barrier.

| Values      | <i>lock</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | The lock object.       |
| Description | The function <b>make-lock</b> creates a lock object. See “Locks” on page 179 for a general description of locks.<br><br><i>name</i> names the lock and can be queried with <b>lock-name</b> . The default value of <i>name</i> is "Anon".<br><br><i>important-p</i> controls whether the lock is automatically freed when the holder process finishes. When <i>important-p</i> is true, the system notes that this lock is important, and automatically frees it when the holder process finishes. <i>important-p</i> should be <b>nil</b> for locks which are managed completely by the application, as it is wasteful to record all locks in a global list if there is no need to free them automatically. This might be appropriate when two processes sharing a lock must both be running for the system to be consistent. If one process |                        |

dies, then the other one kills itself. Thus the system does not need to worry about freeing the lock because no process could be waiting on it forever after the first process dies. The default value of *important-p* is `ni1`.

*safep* controls whether the lock is safe. A safe lock gives an error if `process-unlock` is called on it when it is not locked by the current process, and potentially in other 'dangerous' circumstances. An unsafe lock does not signal these errors. The default value of *safep* is `t`.

*recursivep*, when true, allows the lock to be locked recursively. Trying to lock a lock that is already locked by the current thread just increments its lock count. If the lock is created with *recursivep* `ni1` then trying to lock again causes an error. This is useful for debugging code where the lock is never expected to be claimed recursively. The default value of *recursivep* is `t`.

*sharing*, when true, causes *lock* to be a "sharing" lock object, which supports sharing and exclusive locking. At any given time, an sharing lock may be free, or it may be locked for sharing by any number of threads or locked for exclusive use by a single thread. Sharing locks are handled by different functions and methods from non-sharing locks.

Example

```

CL-USER 3 > (setq *my-lock* (mp:make-lock
 :name "my-lock"))
#<MP:LOCK "my-lock" Unlocked 2008CAC7>

CL-USER 4 > (mp:process-lock *my-lock*)
T

CL-USER 5 > *my-lock*
#<MP:LOCK "my-lock" Locked once by "CAPI Execution
Listener 1" 2008CAC7>

CL-USER 6 > (mp:process-lock *my-lock*)
T

CL-USER 7 > *my-lock*
#<MP:LOCK "my-lock" Locked 2 times by "CAPI Execution
Listener 1" 2008CAC7>

```

## make-mailbox *Function*

|             |                                                               |               |
|-------------|---------------------------------------------------------------|---------------|
| Summary     | Makes a new mailbox.                                          |               |
| Package     | <code>mp</code>                                               |               |
| Signature   | <code>make-mailbox &amp;key size name =&gt; mailbox</code>    |               |
| Arguments   | <code>size</code>                                             | An integer    |
|             | <code>name</code>                                             | A Lisp object |
| Values      | <code>mailbox</code>                                          | A mailbox     |
| Description | The function <code>make-mailbox</code> returns a new mailbox. |               |

*size* specifies the initial size of the mailbox *mailbox*.

The reader process is set to `nil`.

*name* does not affect the functionality of *mailbox*, but can be very useful for debugging. It appears in the printed representation of *mailbox*, and also in the `process-whostate` of any process that waits for *mailbox* (using `mailbox-read`).

| Description      | <p>The function <code>make-named-timer</code> creates and returns a named timer. The first argument is a string or symbol naming the timer. The second argument is a function to be applied to the remaining arguments when the timer expires. Use the function <code>schedule-timer</code> or <code>schedule-timer-relative</code> to set an expiration time.</p> |              |                    |                 |            |                  |                                       |

In comparison, the function `make-timer` creates an unnamed timer.

Example

```
(setq timer (mp:make-named-timer 'timer-1 'print 10
standard-output))

#<Time Event TIMER-1 : PRINT>
```

## make-semaphore

## *Function*

Summary

Makes a semaphore.

Package

`mp`

Signature

```
make-semaphore &key name count => sem
```

Arguments

*name* An object.

*count* A non-negative fixnum.

Values

*sem* A semaphore.

Description

The function `make-semaphore` returns a new semaphore for use with `semaphore-acquire` and `semaphore-release`. The unit count is initialized to *count*, which defaults to 1. If *name* is supplied, the semaphore will have that name. If *name* is not supplied, the semaphore will be given a unique anonymous name.

| Description | <p>The function <b>make-timer</b> creates and returns an unnamed timer. The <i>function</i> argument is a function to be applied to the remaining arguments when the timer expires. Use the function <b>schedule-timer</b> or <b>schedule-timer-relative</b> to set an expiration time.</p> <p>Note that the function <b>make-named-timer</b> creates a named timer.</p> |                                       |
| Example     | <pre>(setq timer       (mp:make-timer 'print 10 *standard-output*)) =&gt; #&lt;Time Event : PRINT&gt;</pre>                                                                                                                                                                                                                                                              |                                       |
| See also    | <b>make-named-timer</b><br><b>make-timer</b><br><b>schedule-timer</b><br><b>schedule-timer-milliseconds</b>                                                                                                                                                                                                                                                              |                                       |

## map-processes

## *Function*

Summary

Calls a predicate function on processes in turn until a true value is returned.

Package

`mp`

Signature

`map-processes function -> result`

Arguments

*function*

A function taking one argument

Values

*result*

A process or `nil`.

Description

The function `map-processes` calls *function* on processes.

*function* is passed each live process (as determined by `process-alive-p`) in turn as its single argument.

For a process argument *p*, if *function* returns `nil` then `map-processes` continues by calling *function* on another process,

but if function returns true then `map-processes` returns *p* immediately and stops calling *function* (so *function* may not get called on all processes).

| Values      | <code>reasons</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | A list of reasons. |
| Description | The function <code>process-arrest-reasons</code> returns a list of the reasons why a Lisp process has stopped. A process is inactive if it has any arrest reasons.<br><br>Use of <code>(setf mp:process-arrest-reasons)</code> is deprecated. You should use <code>process-stop</code> instead. If you set the arrest reasons of the current process, this causes the current process to stop immediately, before returning from <code>mp:process-arrest-reasons</code> (like <code>process-stop</code> ). |                    |

|                    |                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Compatibility note | The immediate stopping behavior of ( <code>setf mp:process-arrest-reasons</code> ) is different from LispWorks 5.0 and previous versions. |
| See also           | <code>process-run-reasons</code><br><code>process-stop</code>                                                                             |

## process-break *Function*

|             |                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------|
| Summary     | Breaks a Lisp process and enters the debugger.                                                                   |
| Package     | <code>mp</code>                                                                                                  |
| Signature   | <code>process-break process =&gt;</code>                                                                         |
| Arguments   | <code>process</code> A process.                                                                                  |
| Values      | None.                                                                                                            |
| Description | The function <code>process-break</code> forces the process <code>process</code> to break and enter the debugger. |

| <i>whostate</i>               | The status of the process while the lock is locked, as seen in the Process Browser.                                                                                                                                                                                                                                                                                                                                                                                       |  |                     |                 |                 |                                                                                     |                |                                 |
| <i>timeout</i>                | A timeout interval, in seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |                     |                 |                 |                                                                                     |                |                                 |
| Description                   | <p>The function <code>process-exclusive-lock</code> is the same as <code>process-lock</code>, but on a "sharing" lock. It waits until the lock is free before locking in exclusive mode.</p> <p>Calls to <code>process-exclusive-lock</code> should be paired with <code>process-exclusive-unlock</code> calls. In most cases the macro <code>with-exclusive-lock</code> the best way to achieve this.</p>                                                                |  |                     |                 |                 |                                                                                     |                |                                 |
| Notes                         | <p>It is not possible to use exclusive lock in the scope of a sharing lock on the same lock, and trying to do this will cause the process to hang. Whether it is possible to use an exclusive lock inside an exclusive lock of the same lock is determined by the <code>recursivelp</code> argument in <code>make-lock</code>.</p> <p><code>process-exclusive-lock</code> is guaranteed to return if it locked process, but may throw before locking, as described in</p> |  |                     |                 |                 |                                                                                     |                |                                 |

**process-exclusive-unlock** *Function*

Summary      Like `process-unlock`, but on a "sharing" lock.

Package      `mp`

Signature      `process-exclusive-unlock sharing-lock`

Arguments      `sharing-lock`      A sharing lock.

Description      The function `process-exclusive-unlock` is the same as `process-unlock` but for a "sharing" lock.

Calls to `process-exclusive-unlock` should be paired with `process-exclusive-lock` calls. In most cases the macro `with-exclusive-lock` the best way to achieve this.

Notes      `process-exclusive-unlock` is guaranteed to successfully unlock the lock, but is not guaranteed to return, as described in “Guarantees and limitations when locking and unlocking” on page 180.

| <b>*process-initial-bindings*</b> | <i>Variable</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Summary                           | Specifies the variables initially bound in a new process.                                                                                                                                                                                                                                                                                                                                                                                                           |
| Package                           | <code>mp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description                       | This specifies the variables that are initially bound in a Lisp process when that process is created. This variable is an association list of symbols and initial value forms. The initial value forms are processed by a simple evaluation that handles symbols and function call forms, but not special operators. As a special case, if the value form is the same as the symbol and that symbol is unbound, then the symbol will be unbound in the new process. |
| Examples                          | <p>This example shows a typical use with a bound symbol:</p> <pre>(defvar *binding-1* 10)</pre>                                                                                                                                                                                                                                                                                                                                                                     |

```

(let ((mp:*process-initial-bindings*
 (cons '(*binding-1* . 20)
 mp:*process-initial-bindings*)))
 (mp:process-run-function
 "binding-1"
 '()
 #'(lambda (stream)
 (format stream "~&Binding 1 is ~S.~%" *binding-1*)
 standard-output)
 (sleep 1)))
=>
Binding 1 is 20.

```

This example shows the special case with an unbound symbol:

```

(defvar *binding-2*)

(let ((mp:*process-initial-bindings*
 (cons '(*binding-2* . *binding-2*)
 mp:*process-initial-bindings*)))
 (flet ((check-binding-2 ()
 (mp:process-run-function
 "binding-2"
 '()
 #'(lambda (stream)
 (if (boundp '*binding-2*)
 (format stream "~&Binding 2 is ~S.~%" *binding-2*)
 (format stream "~&Binding 2 is
unbound.~%")))
 standard-output)
 (sleep 1)))
 (check-binding-2)
 (let ((*binding-2* 123))
 (check-binding-2))))
=>
Binding 2 is unbound.
Binding 2 is 123.

```

## process-internal-server-p

Summary

Tests whether a process is an internal server.

## *Function*

|             |                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>mp</code>                                                                                                                                                          |
| Signature   | <code>process-internal-server-p process =&gt; result</code>                                                                                                              |
| Arguments   | <code>process</code> A <code>mp:process</code> object.                                                                                                                   |
| Values      | <code>result</code> A boolean.                                                                                                                                           |
| Description | The function <code>process-internal-server-p</code> is the predicate for whether a process is marked as "internal server".                                               |
| Notes       | Processes are marked as "internal server" by a true value for <code>:internal-server</code> amongst the <i>keywords</i> in a call to <code>process-run-function</code> . |

|             | <b>Function</b>                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Interrupts a process.                                                                                                                                                                    |
| Package     | <code>mp</code>                                                                                                                                                                          |
| Signature   | <code>process-interrupt process function &amp;rest arguments =&gt;</code>                                                                                                                |
| Arguments   | <code>process</code> A process.<br><code>function</code> A function to apply on resuming <code>process</code> .<br><code>arguments</code> Arguments to supply to <code>function</code> . |
| Values      | None.                                                                                                                                                                                    |
| Description | The function <code>process-interrupt</code> causes the Lisp process <code>process</code> to apply <code>function</code> to <code>arguments</code> when it is next resumed.               |

Afterwards the process resumes its normal execution. A waiting process is temporarily woken up.

## process-join

### *Function*

Summary      Waits until a specified process dies, or a *timeout* is reached.

Package      `mp`

Signature      `process-join process &key timeout => flag`

Arguments      `process`      A process.

`timeout`      A non-negative number.

Values      `flag`      A boolean.

Description      The function `process-join` waits until the process `process` dies, or `timeout` seconds passed.

If the process dies then `process-join` returns `t`. If the timeout passed it returns `nil`.

`process-join` can be used on dead processes, and in this case returns `t` immediately.

The effect of `process-join` is similar to

```
(mp:process-wait-with-timeout
 "Waiting for process to die" timeout
 #'(lambda (x)
 (not (mp:process-alive-p x))) process)
```

but the call above may not return until the next time the scheduler runs, possibly causing a delay. In contrast `process-join` returns immediately when the process dies.

| Description         | The function <code>process-kill</code> kills the specified Lisp process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Notes               | <ol style="list-style-type: none"> <li>1. <code>process-kill</code> works by interrupting the process. Therefore the kill will happen only when the process is processing interrupts. If <code>process-kill</code> is called while the process is in a no-interrupt context, the killing will actually happen when the process exits that no-interrupt context.</li> <li>2. If the killing happens inside the cleanup forms of <code>unwind-protect</code>, it may terminate a cleanup in the middle. It is possible to protect against this by doing all cleanups with interrupts disallowed, but that is not easy. Thus <code>process-kill</code> may be problematic, and should be avoided when possible. Whenever possible, make your processes check some flag that can be set by other threads and exit when the flag is set to some value.</li> </ol> |

|             | <i>whostate</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | The status of the current Lisp process, before <code>process-lock</code> returns, that is, the status while the current process is waiting to time-out. This can be seen in the Process Browser. |
|             | <i>timeout</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | A timeout interval, in seconds. If this is not given, <code>process-lock</code> waits until the lock can be set by the current Lisp process. A process can set a lock more than once.            |
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | A boolean.                                                                                                                                                                                       |
| Description | <p>The function <code>process-lock</code> attempts to lock <i>lock</i> and returns <code>t</code> if successful, or <code>nil</code> if timed out. If <i>lock</i> is already locked and the owner of the lock is the value of <code>*current-process*</code>, then <i>lock</i> remains locked and an internal count is incremented. The Lisp process sleeps until the lock is claimed or the timeout period expires.</p> <p><i>result</i> is <code>t</code> if <i>lock</i> was successfully locked, and <code>nil</code> otherwise.</p> |                                                                                                                                                                                                  |
| Notes       | <p><code>process-lock</code> is guaranteed to return if it locked process, but may throw before locking, as described in “Guarantees and limitations when locking and unlocking” on page 180.</p>                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                  |
| Example     | <pre>(process-lock *my-lock* "waiting to lock" 10)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                  |

| Values      | <code>plist</code>                                                                                                                                                                                                                                                                                | A plist   |
| Description | The function <code>process-plist</code> returns the plist associated with <code>process</code> .                                                                                                                                                                                                  |           |
| Notes       | It is not possible to manipulate the plist in a thread-safe manner, and <code>process-plist</code> may interact badly with other users of the plist, hence <code>process-plist</code> is deprecated. Use instead <code>process-property</code> and <code>get-process-private-property</code> etc. |           |

| process-poke     | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Values           | <code>result</code> A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description      | <p>If the process <code>process</code> is waiting, <code>process-poke</code> causes it to run its <i>wait-function</i> as soon as possible, and if the wait function returns true, the process returns from <code>process-wait</code>.</p> <p>This has an effect only in SMP LispWorks, where the running of the <i>wait-function</i> can happen asynchronously.</p> <p><code>process-poke</code> can be used to avoid delays that happen because the next execution of the <i>wait-function</i> does not happen immediately. Without the call to <code>process-poke</code>, the process may wake up after some delay.</p> <p><code>process-poke</code> returns <code>t</code> if it actually poked the process or <code>nil</code> otherwise (when the process is not waiting or is stopped).</p> |
| Example          | <pre>(my-queue-an-event-for-the-workers)  (dolist (process *my-worker-processes*)   (when (mp:process-poke process) (return)))</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| See also         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| process-priority | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Summary          | Returns the numerical priority of the Lisp process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|             |                                                      |                                                                                                                            |
|-------------|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>mp</code>                                      |                                                                                                                            |
| Signature   | <code>process-priority process =&gt; priority</code> |                                                                                                                            |
| Arguments   | <code>process</code>                                 | A process.                                                                                                                 |
| Values      | <code>priority</code>                                | A fixnum, the priority of <code>process</code> .                                                                           |
| Description |                                                      | Returns the numerical priority of the Lisp process. This can be modified by calling <code>change-process-priority</code> . |
| Example     |                                                      | <code>CL-USER 17 &gt; (mp:process-priority mp:*current-process*)</code><br><code>600000</code>                             |

## **process-private-property** *Function*

|             |                                                                                                                                                 |                                            |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| Summary     | Gets or sets the value of a private property of the current process.                                                                            |                                            |
| Package     | <code>mp</code>                                                                                                                                 |                                            |
| Signature   | <code>process-private-property indicator &amp;optional default =&gt; result</code>                                                              |                                            |
|             | <code>(setf process-private-property) value indicator &amp;optional default =&gt; result</code>                                                 |                                            |
| Arguments   | <code>indicator</code>                                                                                                                          | A Lisp object.                             |
|             | <code>default</code>                                                                                                                            | A Lisp object.                             |
| Values      | <code>result</code>                                                                                                                             | <code>value</code> or <code>default</code> |
| Description | The function <code>process-private-property</code> gets or sets the value that is associated with <code>indicator</code> in the private proper- |                                            |

ties of the current process (that is, the result of calling `get-current-process`).

If *indicator* is not associated with a value in the private properties, `process-private-property` returns *default*.

`(setf process-private-property)` overwrites any existing value for *indicator*.

The default value of *default* is `nil`.

- Notes
1. Private properties can be read from other processes using `get-process-private-property`, but cannot be set by other processes.
  2. Process private property access is faster than than process property access in SMP LispWorks, because the implementation of the latter must deal with parallel setting.

|             |                                                                                                                                                                                                                                                                                                                                                                 |                               |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                   | A property value, or default. |
| Description | The function <code>process-property</code> gets the value that is associated with <i>indicator</i> for the process <i>process</i> , and <code>(setf process-property)</code> sets this value.<br><br>If <i>process</i> is not supplied or is <code>nil</code> , the current process (that is, the result of calling <code>get-current-process</code> ) is used. |                               |
| Notes       | In the typical case when only the current process sets the property (even if other processes read it), private properties can be used, and are much faster in SMP LispWorks, because they do not need to deal with parallel setting. See <code>process-private-property</code> .                                                                                |                               |
| Example     | <pre>(process-property 'foo (get-current-process) 'bar) =&gt; BAR  (setf (process-property 'foo) 'foo-value) =&gt; FOO-VALUE  (process-property 'foo) =&gt; FOO-VALUE</pre>                                                                                                                                                                                     |                               |

| Signature | <code>process-reset process =&gt;</code>          |                 |

|             |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments   | <i>process</i> | A process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Values      | None.          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description |                | <p><b>process-reset</b> interrupts the execution of <i>process</i> and “throws away” its current state. Upon resuming execution, the process calls its function with its initial argument and priority.</p> <p><b>process-reset</b> modifies the dynamic execution state of <i>process</i>. It performs a non-local exit from the currently running function, to cause the process's main function to return. <b>unwind-protect</b> forms will be run.</p> <p><b>process-reset</b> does not modify any of the attributes of the process, in particular its priority, items on the plist, or accumulated run-time.</p> |
| Notes       |                | Since <b>process-reset</b> causes an asynchronous non-local exit, it is possible that it can occur within an <b>unwind-protect</b> cleanup form or before data used by an <b>unwind-protect</b> cleanup form has been initialized. In some cases, not all cleanups within that form will be run.                                                                                                                                                                                                                                                                                                                      |

|           |                                                     | <i>Function</i>                                                                                           |
|-----------|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| Summary   | Create a new process, passing it a function to run. |                                                                                                           |

|             | <i>arguments</i> | Arguments to pass to <i>function</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Values      | <i>process</i>   | The newly created process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description |                  | <p>This function creates a new Lisp process with name <i>name</i>. Other properties of <i>process</i> may be specified in keyword/value pairs in <i>keywords</i>:</p> <ul style="list-style-type: none"> <li><b>:priority</b> A <code>fixnum</code> representing the priority for the process. If <code>:priority</code> is not supplied, the process priority becomes the value of the variable <code>*default-process-priority*</code>.</li> <li><b>:mailbox</b> A mailbox object, a string, <code>t</code> or <code>nil</code>, used to initialize the <code>process-mailbox</code> of <i>process</i>. True values specify that <i>process</i> should have a mailbox. A mailbox object is used as-is; a string is used as the name of a new mailbox; and <code>t</code> causes it to create a mailbox with the same name as <i>process</i>, that is, <i>name</i>. Note that both <code>process-send</code> and <code>process-wait-for-event</code> force the relevant process to have a mailbox.</li> <li><b>:internal-server</b> When true, this indicates that the process is an "internal server", which means that it responds to requests for work from other processes. The main effect of this is that if the only processes that remain are "internal servers", nothing is going to happen, so LispWorks quits. The system marks some of the processes that it creates as "internal server".</li> </ul> <p>The new process is preset to apply <i>function</i> to <i>arguments</i> and runs in parallel, while <code>process-run-function</code> returns immediately.</p> |

**Example**

```

CL-USER 253 > (defvar *stream* *standard-output*)
STREAM

CL-USER 254 > (mp:process-run-function
 "My process"
 '(:priority 42)
 #'(lambda (x)
 (loop for i below x
 do (and (print i *stream*)
 (sleep 1)))
 finally
 (print (mp:process-priority
 mp::*current-process*)
 stream)))
3)
#<MP:PROCESS Name "My process" Priority 850000 State
"Running">

0
1
2
42
CL-USER 255 >

```

**process-run-reasons***Function***Summary**

Returns the reasons that a specified process is running.

**Package**

**mp**

**Signature**

**process-run-reasons *process* => *reasons***

**(setf process-run-reasons) *process* *reasons* => *reasons***

**Arguments**

***process***

A process.

**Values**

***reasons***

A list of run reasons.

|             |                                                                                                                                                                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>process-run-reasons</code> returns a list of reasons for the specified Lisp process running. These can be changed using <code>setf</code> .<br><br>A process is only active if it has at least one run reason and no arrest reasons. |
| See also    | <code>process-arrest-reasons</code><br><code>process-run-function</code><br><code>process-whostate</code>                                                                                                                                               |

|             | <i>Function</i>                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns the current run time for a process.                                                                                                                                                                                                 |
| Package     | <code>mp</code>                                                                                                                                                                                                                             |
| Signature   | <code>process-run-time process =&gt; time</code>                                                                                                                                                                                            |
| Arguments   | <code>process</code> A process.                                                                                                                                                                                                             |
| Values      | <code>time</code> A positive integer or <code>nil</code> .                                                                                                                                                                                  |
| Description | The function <code>process-run-time</code> returns the current run time for <code>process</code> in internal time units. If the value cannot be determined (currently this is only on FreeBSD), then the return value is <code>nil</code> . |
| Notes       | The value returned by <code>get-internal-run-time</code> is similar, but on some operating systems it is the total time for all Lisp processes in the image.                                                                                |
| See also    | <code>process-idle-time</code>                                                                                                                                                                                                              |

| process-send                 | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                      |           |                     |           |                              |                                                                        |

| Description                  | <p>The function <code>process-send</code> queues <i>object</i> in the mailbox of the given process.</p> <p><i>object</i> can any kind of Lisp object, and it is up to the receiving process to interpret it.</p> <p><code>process-send</code> only sends the event: it is the responsibility of the receiving process to actually read the event and then interpret it. Reading is typically done by calling <code>process-wait-for-event</code>. Interpreting the event is up the caller of <code>process-wait-for-event</code>.</p> <p><code>process-send</code> actually uses the <code>process-mailbox</code> of <i>process</i>, creating a mailbox for <i>process</i> if it does not already have one. In principle <i>object</i> can be read by another process, by calling <code>mailbox-read</code> (or <code>process-wait-for-event</code>) on the mailbox.</p> <p>If <i>change-priority</i>, which has a default value of <code>:default</code>, is non-nil, it controls how the priority of that process is calculated as follows:</p> <ul style="list-style-type: none"> <li>• <code>fixnum</code> — use the value of <i>change-priority</i> as the new priority.</li> <li>• <code>t</code> — set the priority to the interactive priority.</li> </ul> |                      |           |                     |           |                              |                                                                        |

- `:default` — set the priority to the normal running priority.

| <i>sharing-lock</i> | A sharing lock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                     |                 |                 |                                                                                     |                |                               |
| <i>whostate</i>     | The status of the process while the lock is locked, as seen in the Process Browser.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                     |                 |                 |                                                                                     |                |                               |
| <i>timeout</i>      | A timeout period, in seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                     |                 |                 |                                                                                     |                |                               |
| Description         | <p>This is like <code>process-lock</code>, but the lock must be "sharing" and the lock will be locked in shared mode. That means that other threads can also lock it in shared mode.</p> <p>Before locking this waits for the lock to be free of any exclusive lock, but it does not check for other shared mode use of the same lock.</p> <p>Calls to <code>process-sharing-lock</code> should be matched by calls to <code>process-sharing-unlock</code>. Normally <code>with-sharing-lock</code> is the best way to achieve this.</p> |                     |                 |                 |                                                                                     |                |                               |
| Notes               | <p>It is possible to lock for sharing inside the scope of sharing lock and inside the scope of exclusive lock.</p> <p><code>process-sharing-lock</code> is guaranteed to return if it locked process, but may throw before locking, as described in</p>                                                                                                                                                                                                                                                                                  |                     |                 |                 |                                                                                     |                |                               |

|             |                                                                                                                                                                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Removes a sharing lock.                                                                                                                                                                                                                                                                                                    |
| Package     | <code>mp</code>                                                                                                                                                                                                                                                                                                            |
| Signature   | <code>process-sharing-unlock <i>sharing-lock</i></code>                                                                                                                                                                                                                                                                    |
| Arguments   | <code>sharing-lock</code> A sharing lock.                                                                                                                                                                                                                                                                                  |
| Description | <p>The function <code>process-sharing-unlock</code> is the same as <code>process-unlock</code> but for a "sharing" lock.</p> <p>Calls to <code>process-sharing-unlock</code> should be matched by calls to <code>process-sharing-lock</code>. Normally <code>with-sharing-lock</code> is the best way to achieve this.</p> |
| Notes       | <code>process-sharing-unlock</code> is guaranteed to successfully unlock the lock, but is not guaranteed to return, as described in “Guarantees and limitations when locking and unlocking” on page 180.                                                                                                                   |
| See also    | <code>process-unlock</code><br><code>with-sharing-lock</code>                                                                                                                                                                                                                                                              |

## **process-stop** *Function*

Summary      Stops a process.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Arguments   | <code>process</code> A <code>mp:process</code> object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description | <p>The function <code>process-stop</code> stops the process <code>process</code>. <code>process</code> must be a full process (that is, not one created by <code>*current-process*</code>).</p> <p><code>process-stop</code> causes <code>process</code> to stop until some other process explicitly wakes it up. If it is called on the current process, the current process stops during the call, and returns from <code>process-stop</code> after the process gets woken up.</p> <p>In SMP LispWorks, if <code>process</code> is not the current process, <code>process-stop</code> returns immediately and the execution of <code>process</code> stops at some point, possibly after <code>process-stop</code> returned. In non-SMP LispWorks if <code>process</code> is not the current process, <code>process</code> stops before <code>process-stop</code> returns.</p> <p>You can wake up a stopped process (that is, make it runnable) by calling <code>process-kill</code>, <code>process-unstop</code> or <code>process-continue</code>.</p> <p><code>process-interrupt</code> does not wake up a stopped process.</p> <p>There is a discussion of a typical use of <code>process-stop</code> in the section “Stopping and unstopping processes” on page 174.</p> <p><code>process-stop</code> does not return any useful value.</p> |

| Arguments   | <code>lock</code>                                                                                                                                 | The lock to be relinquished.                                                                                                                           |
|             | <code>errorp</code>                                                                                                                               | When this is <code>t</code> , an error is signalled if <code>*current-process*</code> is not the owner of the lock.<br>The default is <code>t</code> . |
| Values      | <code>result</code>                                                                                                                               | A boolean.                                                                                                                                             |
| Description | Attempts to release a lock. If the lock is owned by <code>*current-process*</code> , <code>process-unlock</code> decrements an internal count. If |                                                                                                                                                        |

this lock count is then zero, the lock is released. Note that `process-unlock` relates only on Lisp processes.

*result* is `t` if the lock was released, and `nil` otherwise.

|          |                                                                                                                                                                                                          |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>process-sharing-unlock</code> is guaranteed to successfully unlock the lock, but is not guaranteed to return, as described in “Guarantees and limitations when locking and unlocking” on page 180. |

|             | <code>wait-arguments</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | The arguments that <code>wait-function</code> is applied to. |
| Values      | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                              |
| Description | <p>The function <code>process-wait</code> suspends the current Lisp process until the predicate <code>wait-function</code> applied to <code>wait-arguments</code> returns <code>t</code>. This is tested periodically.</p> <p><code>wait-function</code> has several limitations: it must not do a non-local exit, it should not have side effects and (since it is called frequently) it should be efficient.</p> <p><code>wait-reason</code> allows you to find out why a process is waiting via the function <code>process-whostate</code>.</p> |                                                              |

| Description | The function <code>process-wait-local</code> has same semantics as <code>process-wait</code> , but is "local", which here means that it does not interact with the scheduler. The scheduler does not call the wait function and hence never wakes the waiting process |                               |

The wait function is called only by the calling process, before going to sleep, and whenever it is "poked". A process is typically "poked" by calling `process-poke`, but all the other process managing functions (`process-unstop`, `process-interrupt`, `process-kill`) also "poke" the process. Returning from any of the generic Process Waiting functions (see "Generic Process Wait functions" on page 182) or `cl:sleep` also implicitly pokes the process. A process may be also poked internally.

Because the wait function is checked only when the process is poked, it is the responsibility of the application to poke the process when it should check the wait function. This is the disadvantage of `process-wait-local` and `process-wait-local-with-timeout`.

**Note:** See `process-wait-local-with-periodic-checks` and `process-wait-local-with-timeout-and-periodic-checks` for functions that periodically check the wait functions.

One advantage of using the "local" waiters is that the wait function is called only by the waiting process. This means that the wait function does not have any of the restrictions that the wait function of `process-wait` has. In particular:

1. It does not matter if the wait function is not very fast.  
Note however, that it may be called several times, and not always in a predictable way, so it is better not to make it too slow or allocate much. You also cannot rely on any side effect that is cumulative inside the wait function, except in the call that returns `t` (because this happens at most once).
2. If there is an unhandled error in the wait function it enters the debugger like normal Lisp code, so it is easier to debug.

3. The wait function is in the dynamic scope of the calling process, and so it sees all the dynamic bindings and can throw to all the catchers. That also means that all the handlers and restarts of the calling process are applicable in the wait function.
4. The wait function can itself call Process Waiting functions or `c1:sleep`, with a small caveat: since these functions may implicitly "poke" the process, if the wait function calls any of them and then returns `nil`, it may be immediately called again (if it returns `t` then `process-wait-local` itself returns). Normally this is not a problem, because it is still waiting, but it does mean that the wait function is called more times than expected.
5. The wait function, because it can call Process Waiting functions, can use locks without causing errors. Note, however, that if the lock is held, it will cause an internal call to a Process Waiting function, which will "poke" the process and hence cause another call of the wait function (unless it returns `t`).
6. The wait function is visible in the output of the profiler.

Another advantage of the "local" functions is that they do not interact with the scheduler and so they reduce the overhead of the scheduler.

`process-wait-local` always returns `t`.

|             | <i>args</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Arguments passed to <i>function</i> . |
| Description | <p>The function <code>process-wait-local-with-periodic-checks</code> is like <code>process-wait-local</code>, but also calls the wait function periodically.</p> <p>The <i>period</i> is in seconds.</p> <p>After each call to the function <i>wait-function</i>, the process sleeps at most <i>period</i> seconds, and then checks the wait function. If the process is poked while sleeping, it wakes up, checks the wait function, and then (if the wait function returns <code>nil</code>), sleeps again for at most <i>period</i> seconds.</p>                                                                                                                                                                                                                                             |                                       |
| Notes       | <p>The resolution of the period is dependent on the underlying operating system. Many systems give time-slices of few milliseconds, so the actual period may be out by a few milliseconds. In general, periods of 0.1 seconds or more are reasonably reliable, though not exact. Shorter periods become less and less reliable.</p> <p>If the period is short, the wait function is called frequently, and hence there is more overhead for the system. With a reasonable wait function and a period of 0.1 or more, this overhead is probably insignificant. If you use shorter periods, or an expensive wait function, you may want to check what the overhead is. The easiest way to check is to make sure your system is such that the wait function returns <code>nil</code>, then run</p> |                                       |

```
(ignore-errors ; just in case
 (sys:with-other-threads-disabled
 (time (mp:process-wait-local-with-timeout-and-
periodic-checks
 "Timing" 5 period function args))))
```

When this form returns, compare the user and system times (which is what it actually used) to the elapsed time (which should be approximately 5 seconds). That will tell you what fraction of a "CPU" is used by the call. If the user and system time are less than 0.01 seconds, you may want to increase the time to get a more accurate number.

Warning: inside the scope of `with-other-threads-disabled`, the rest of the threads are disabled. So if your wait function ends up waiting for something that has to happen on another thread, your system will be deadlocked.

## process-wait-local-with-timeout *Function*

Summary      Has the same semantics as `process-wait-with-timeout`, but does not interact with the scheduler.

Package      `mp`

Signature      `process-wait-local-with-timeout wait-reason timeout function &rest args => result`

Arguments      `wait-reason`      A string.

`timeout`      A non-negative number.

`function`      A function designator.

`args`      Arguments passed to function.

| Values                 | <code>count</code> | A non-negative integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Description            |                    | <p>The function <code>processes-count</code> returns the number of Lisp processes that are currently alive.</p> <p>The <code>count</code> includes all processes that are alive, that is started executing and did not die. It does not include any thread that was started by foreign code, unless it calls into Lisp, in which case Lisp automatically generates a matching Lisp process which is included in the count.</p> <p>In general processes can start and die so the real count may change by the time the function has returned. The only guarantee is that the count was accurate at some point between the time <code>processes-count</code> was called and the time it returns.</p> |

| Package                            |                  | <code>mp</code>                                                                             |
| Signature                          |                  | <code>pushnew-to-process-property indicator value &amp;key process test =&gt; result</code> |
| Arguments                          | <i>indicator</i> | A Lisp object.                                                                              |
|                                    | <i>value</i>     | A Lisp object.                                                                              |
|                                    | <i>process</i>   | A process, or <code>nil</code> .                                                            |
|                                    | <i>test</i>      | A function designator for a function of two arguments.                                      |
| Values                             | <i>result</i>    | A list.                                                                                     |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>pushnew-to-process-property</code> pushes <i>value</i> to the value of the property associated with <i>indicator</i> for the process <i>process</i>. It uses the function <code>test</code> to compare existing property values of <i>process</i> with <i>value</i> and does not push if one matches, in the same way as <code>cl:pushnew</code>.</p> <p>The default value of <code>test</code> is <code>#'eq</code>.</p> <p>If there is a property associated with <i>indicator</i>, the value of the property must be a list.</p> <p>If <i>process</i> is not supplied or is <code>nil</code>, the current process (that is, the result of calling <code>get-current-process</code>) is used.</p> <p><i>result</i> is the new value of the process property.</p> <p>The modification is done in a thread-safe way.</p> |
| Notes       | In the typical case when only the current process sets the property (even if other processes read it), private properties can be used, and are much faster in SMP LispWorks, because they do not need to deal with parallel setting. See <code>process-private-property</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>ps</b> |  | <i>Function</i>                    |
|-----------|--|------------------------------------|
| Summary   |  | Prints the processes in the system |
| Package   |  | <code>mp</code>                    |
| Signature |  | <code>ps =&gt;</code>              |
| Arguments |  | None.                              |
| Values    |  | None.                              |

Description Prints a list of the processes in the system, ordered by priority. (This function is analogous to the UNIX command `ps`.)

## **remove-from-process-private-property** *Function*

Summary Removes a value from a private property of the current process.

Package `mp`

Signature `remove-from-process-private-property indicator value &key test => result`

Arguments *indicator* A Lisp object.

*value* A Lisp object.

Values *result* A list.

Description The function `remove-from-process-private-property` removes *value* from the value of the private property associated with *indicator* for the current process.

It behaves just like `remove-from-process-property`.

`get-process-private-property`

## **remove-from-process-property** *Function*

Summary Removes a value from a general property of a process.

Package `mp`

| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | A list.                                                |
| Description | <p>The function <code>remove-from-process-property</code> removes <i>value</i> from the value of the property associated with <i>indicator</i> for the process <i>process</i>. It uses the function <i>test</i> to compare <i>value</i> with existing values, in the same way as <code>cl:remove</code>.</p> <p>The default value of <i>test</i> is <code>#'eql</code>.</p> <p>If there is a property associated with <i>indicator</i>, the value of the property must be a list.</p> <p>If <i>process</i> is not supplied or is <code>nil</code>, the current process (that is, the result of calling <code>get-current-process</code>) is used.</p> <p><i>result</i> is the new value of the process property.</p> <p>The modification is done in a thread-safe way.</p> |                                                        |
| Notes       | <p>In the typical case when only the current process sets the property (even if other processes read it), private properties can be used, and are much faster in SMP LispWorks, because they do not need to deal with parallel setting. See <code>process-private-property</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                        |

| Values      | <i>removedp</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | A generalized boolean. |
| Description | <p>The function <code>remove-process-private-property</code> removes the property associated with <i>indicator</i> from the private properties of the current process.</p> <p>Note that removing a property is different from setting its value to <code>nil</code>, because when <code>process-private-property</code> is called with a <i>default</i> for a property that was removed, it returns the <i>default</i>, but for a property that was set to <code>nil</code> it returns <code>nil</code>.</p> |                        |

| Arguments   | <i>indicator</i> | A Lisp object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|             | <i>process</i>   | A process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Values      | <i>removedp</i>  | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description |                  | <p>The function <code>remove-process-property</code> removes the general property associated with <i>indicator</i> from the process <i>process</i>.</p> <p>If <i>process</i> is not supplied or is <code>nil</code>, the current process (that is, the result of calling <code>get-current-process</code>) is used.</p> <p>Note that removing a property is different from setting its value to <code>nil</code>, because when <code>process-property</code> is called with a default for a property that was removed, it returns the default, but for a property that was set to <code>nil</code> it returns <code>nil</code>.</p> <p><i>removedp</i> is true if the property was removed.</p> |
| Notes       |                  | In the typical case when only the current process sets the property (even if other processes read it), private properties can be used, and are much faster in SMP LispWorks, because they do not need to deal with parallel setting. See <code>process-private-property</code> .                                                                                                                                                                                                                                                                                                                                                                                                                |

## schedule-timer-milliseconds

*Function*

Summary      Schedules a timer to expire after a given amount of time.

Package      `mp`

Signature      `schedule-timer-milliseconds timer absolute-expiration-time &optional repeat-time => timer`

Arguments      `timer`      A timer.  
`absolute-expiration-time`      A non-negative real.  
`repeat-time`      A non-negative real.

Values      `timer`      A timer.

Description      The function `schedule-timer-milliseconds` schedules a timer to expire at a given time after the start of the program. The `timer` argument is a timer returned by `make-timer` or `make-named-timer`. The `absolute-expiration-time` argument is a non-negative real number of milliseconds since the start of the program at which the timer is to expire. If `repeat-time` is

specified, it is a non-negative real number of milliseconds that specifies a repeat interval. Each time the timer expires, it is rescheduled to expire after this repeat interval.

If the timer is already scheduled to expire at the time this function is called, it is rescheduled to expire at the time specified by the *absolute-expiration-time* argument. If that argument is `nil`, the timer is not rescheduled, but the repeat interval is set to the interval specified by the *repeat-time* argument.

The function `schedule-timer-relative-milliseconds` schedules a timer to expire at a time relative to the call to that function.

**Example** The following example schedules a timer to expire 15 minutes after the start of the program and every 5 minutes thereafter.

```
(setq timer
 (mp:make-timer 'print 10 *standard-output*))

#<Time Event : PRINT>

(mp:schedule-timer-milliseconds timer 900000 300000)

#<Time Event : PRINT>
```

## **schedule-timer-relative**

## *Function*

**Summary** Schedules a timer to expire at a given time after this function is called.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                     |

| Description | <p>The function <code>schedule-timer-relative</code> schedules a timer to expire at a given time after the call to the function. The <code>timer</code> argument is a timer returned by <code>make-timer</code> or <code>make-named-timer</code>. The <code>relative-expiration-time</code> argument is a non-negative real number of seconds after the call to the function at which the timer is to expire. If <code>repeat-time</code> is specified, it is a non-negative real number of seconds that specifies a repeat interval. Each time the timer expires, it is rescheduled to expire after this repeat interval.</p> <p>If the timer is already scheduled to expire at the time this function is called, it is rescheduled to expire at the time specified by the <code>relative-expiration-time</code> argument. If that argument is <code>nil</code>, the timer is not rescheduled, but the repeat interval is set to the interval specified by the <code>repeat-time</code> argument.</p> <p>The function <code>schedule-timer</code> schedules a timer to expire at a time relative to the start of the program.</p> |                     |

## **schedule-timer-relative-milliseconds** *Function*

**Summary** Schedules a timer to expire at a given time after this function is called.

**Package** `mp`

**Signature** `schedule-timer-relative-milliseconds timer relative-expiration-time &optional repeat-time => timer`

**Arguments** `timer` A timer.

`relative-expiration-time` A non-negative real.

`repeat-time` A non-negative real.

**Values** `timer` A timer.

**Description** The function `schedule-timer-relative-milliseconds` schedules a timer to expire at a given time after the call to the function. The `timer` argument is a timer returned by `make-timer` or `make-named-timer`. The `relative-expiration-time` argument is a non-negative real number of milliseconds after the call to the function at which the timer is to expire. If

*repeat-time* is specified, it is a non-negative real number of milliseconds that specifies a repeat interval. Each time the timer expires, it is rescheduled to expire after this repeat interval.

If the timer is already scheduled to expire at the time this function is called, it is rescheduled to expire at the time specified by the *relative-expiration-time* argument. If that argument is `nil`, the timer is not rescheduled, but the repeat interval is set to the interval specified by the *repeat-time* argument.

The function `schedule-timer-milliseconds` schedules a timer to expire at a time relative to the start of the program.

#### Example

The following example schedules a timer to expire 5 seconds after the call to `schedule-timer-relative-milliseconds` and every 5 seconds thereafter.

```
(setq timer
 (mp:make-timer 'print 10 *standard-output*))

#<Time Event : PRINT>

(mp:schedule-timer-relative-milliseconds timer 5000
 5000)

#<Time Event : PRINT>
```

## semaphore-acquire

*Function*

#### Summary

Acquires units from a semaphore.

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                  |              |                      |                      |                          |                                |                    |                        |

| Description              | <p>The function <code>semaphore-acquire</code> acquires <code>count</code> units from the semaphore <code>sem</code>.</p> <p>It attempts to atomically decrement the semaphore's unit count by <code>count</code>. If this gives a non negative result, then it changes the semaphore's unit count accordingly and returns true. The default value of <code>count</code> is 1.</p> <p>However, if decrementing the semaphore's unit count would result in a negative number then <code>semaphore-acquire</code> waits until the semaphore's unit count is larger than <code>count</code> and tries again. If <code>wait-reason</code> is true, then it is used as the thread's <code>wait-reason</code> when waiting for the semaphore.</p> <p>If <code>timeout</code> is <code>nil</code>, <code>semaphore-acquire</code> can wait forever. If <code>timeout</code> is true, it should be an integer. If the semaphore count cannot be decremented within <code>timeout</code> seconds, then <code>semaphore-acquire</code> returns false and the semaphore is unaffected. Pass <code>timeout 0</code> if you do not want to wait at all.</p> |                  |              |                      |                      |                          |                                |                    |                        |
| Notes                    | You can get the current unit count of a semaphore by calling <code>semaphore-count</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                  |              |                      |                      |                          |                                |                    |                        |

## **semaphore-count**

*Function*

|             |                                                                                                                                                                                          |                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Summary     | Gets the current unit count of a semaphore.                                                                                                                                              |                        |
| Package     | <code>mp</code>                                                                                                                                                                          |                        |
| Signature   | <code>semaphore-count <i>sem</i> =&gt; <i>count</i></code>                                                                                                                               |                        |
| Arguments   | <code>sem</code>                                                                                                                                                                         | A semaphore.           |
| Values      | <code>count</code>                                                                                                                                                                       | A non negative fixnum. |
| Description | The function <code>semaphore-count</code> returns the current unit count of the semaphore <code>sem</code> . The value is 0 if the semaphore has no unit remaining.                      |                        |
| Notes       | <p>The current unit count value can change in the semaphore after calling <code>semaphore-count</code>.</p> <p>The value returned by <code>semaphore-count</code> is never negative.</p> |                        |
| See also    | <code>make-semaphore</code><br><code>semaphore-acquire</code><br><code>semaphore-release</code><br><code>semaphore-wait-count</code>                                                     |                        |

## **semaphore-name**

*Function*

|           |                                                          |              |
|-----------|----------------------------------------------------------|--------------|
| Summary   | Gets the name of a semaphore.                            |              |
| Package   | <code>mp</code>                                          |              |
| Signature | <code>semaphore-name <i>sem</i> =&gt; <i>name</i></code> |              |
| Arguments | <code>sem</code>                                         | A semaphore. |
| Values    | <code>name</code>                                        | An object.   |

Description      The function `semaphore-name` returns the name that semaphore `sem` was given when it was created.

See also      `make-semaphore`

## semaphore-release

*Function*

Summary      Releases units back to a semaphore.

Package      `mp`

Signature      `semaphore-release sem &key count => flag`

Arguments      `sem`      A semaphore.

`count`      A non negative fixnum.

Values      `flag`      A generalized boolean.

Description      The function `semaphore-release` releases `count` units back to the semaphore `sem`.

It atomically increments the semaphore's unit count by `count` (which defaults to 1).

The returned `flag` is true if any other thread was waiting for the semaphore and false otherwise

`semaphore-wait-count`

## semaphore-wait-count

*Function*

Summary      Get the current wait count of a semaphore.

|             |                                                                                                                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>mp</code>                                                                                                                                                                                                                                   |
| Signature   | <code>semaphore-wait-count sem =&gt; wait-count</code>                                                                                                                                                                                            |
| Arguments   | <code>sem</code> A semaphore.                                                                                                                                                                                                                     |
| Values      | <code>wait-count</code> A non negative fixnum.                                                                                                                                                                                                    |
| Description | The function <code>semaphore-wait-count</code> returns the current number of units that other threads are waiting for from the semaphore <code>sem</code> . The value <code>wait-count</code> is 0 if the semaphore has no thread waiting for it. |
| Notes       | The value can change in the semaphore after calling <code>semaphore-wait-count</code> .                                                                                                                                                           |
| See also    | <code>make-semaphore</code><br><code>semaphore-acquire</code><br><code>semaphore-count</code><br><code>semaphore-release</code>                                                                                                                   |

|             | <i>Function</i>                                                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | A variant of <code>lock-and-condition-variable-wait</code> with a simpler lambda list.                                                                                                                                                                                                                                                                        |
| Package     | <code>mp</code>                                                                                                                                                                                                                                                                                                                                               |
| Signature   | <code>simple-lock-and-condition-variable-wait lock lock-timeout condvar condvar-timeout predicate &amp;rest args</code>                                                                                                                                                                                                                                       |
| Description | The function <code>simple-lock-and-condition-variable-wait</code> is a variant of <code>lock-and-condition-variable-wait</code> that does not take keyword arguments. Also it takes the arguments of the <code>predicate</code> as <code>&amp;rest</code> . It interprets and acts on the arguments just like <code>lock-and-condition-variable-wait</code> . |

`simple-lock-and-condition-variable-wait` returns the result of the *predicate* or the wait, like `lock-and-condition-variable-wait` when *return-function* is not supplied.

|          |                                                                                                                                                                                                                                                                                                  |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>simple-lock-and-condition-variable-wait</code> does not take wait reason arguments, so you should give names to the lock <i>lock</i> and the condition variable <i>condvar</i> for debugging (by passing <i>name</i> in <code>make-lock</code> and <code>make-condition-variable</code> ). |

|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>symeval-in-process</code> reads the value of the symbol <i>symbol</i> in the process <i>process</i> if it is bound dynamically. The global value of <i>symbol</i> is never returned.</p> <p>If <i>symbol</i> is not bound in <i>process</i>, then <i>value</i> and <i>flag</i> are both <code>nil</code>. If <i>symbol</i> is bound in <i>process</i> but <code>makunbound</code> has been called within the dynamic scope of the binding, <i>value</i> is <code>nil</code> and <i>flag</i> is <code>:unbound</code>. Otherwise, <i>value</i> is the value of <i>symbol</i> and <i>flag</i> is <code>t</code>.</p> |
|             | In addition, the form                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|             | <pre>(setf (symeval-in-process symbol process) value)</pre> <p>sets the value of <i>symbol</i> to <i>value</i> in <i>process</i>. It is an error if <i>process</i> has no binding for <i>symbol</i>. This <code>setf</code> form returns <i>value</i> as specified by Common Lisp.</p>                                                                                                                                                                                                                                                                                                                                                   |
| Notes       | <code>symeval-in-process</code> is mostly intended for debugging. It is OK to call it on a thread known to be idle, or in <code>process-wait</code> or <code>process-stop</code> , but it should not be called while the thread is running.                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>timer-expired-p</b> |                                          | <i>Function</i>                                                            |

| Arguments              | <code>timer</code><br><code>delta</code> | A timer<br>A non-negative real                                             |
| Values                 | <code>bool</code>                        | A boolean                                                                  |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>timer-expired-p</code> returns <code>t</code> if the specified timer is not scheduled to expire or is scheduled to expire within the number of seconds specified by the <i>delta</i> argument after the call to <code>timer-expired-p</code> . Otherwise, the function returns <code>nil</code> .<br><br>The <i>timer</i> argument is a timer, returned by <code>make-timer</code> or <code>make-named-timer</code> . The <i>delta</i> argument, if supplied, is a non-negative real number of seconds. |
| Example     | <pre>(setq timer       (mp:make-timer 'print 10 *standard-output*))  #&lt;Time Event : PRINT&gt;  (mp:schedule-timer-relative timer 5)  #&lt;Time Event : PRINT&gt;  (mp:timer-expired-p timer)  NIL</pre>                                                                                                                                                                                                                                                                                                                 |

| Arguments   | <i>timer</i>                                                                                                                                                                                                                                                                                                                                                                                                                          | A timer  |
| Values      | <i>name</i>                                                                                                                                                                                                                                                                                                                                                                                                                           | A string |
| Description | <p>The function <code>timer-name</code> returns the name of the specified <i>timer</i>. The <i>timer</i> argument is a timer returned by <code>make-timer</code> or <code>make-named-timer</code>. If the timer has no name, <code>timer-name</code> returns <code>nil</code>.</p> <p>The name of a timer created by either <code>make-timer</code> or <code>make-named-timer</code> can be set by means of the following syntax:</p> |          |
|             | <pre>(setf (mp:timer-name timer) name)</pre>                                                                                                                                                                                                                                                                                                                                                                                          |          |
| Example     | <pre>(setq timer       (mp:make-timer 'print 10 *standard-output*))  #&lt;Time Event : PRINT&gt;  (mp:timer-name timer)  NIL  (setf (mp:timer-name timer) 'timer-1)  TIMER-1  (mp:timer-name timer)  TIMER-1</pre>                                                                                                                                                                                                                    |          |

## **unschedule-timer** *Function*

|             |                                                                                                                                                                                                                                    |                             |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|
| Summary     | Unschedules a scheduled timer                                                                                                                                                                                                      |                             |
| Package     | <code>mp</code>                                                                                                                                                                                                                    |                             |
| Signature   | <code>unschedule-timer timer =&gt; result</code>                                                                                                                                                                                   |                             |
| Arguments   | <code>timer</code>                                                                                                                                                                                                                 | A timer                     |
| Values      | <code>result</code>                                                                                                                                                                                                                | A timer or <code>nil</code> |
| Description | <p>If the specified timer has been scheduled to expire at a time after the call to <code>unschedule-timer</code>, this function unschedules the timer and returns the timer. Otherwise, the function returns <code>nil</code>.</p> |                             |

The argument is a timer, returned by `make-timer` or `make-named-timer`.

**Example**

```
(setq timer
 (mp:make-timer 'print 10 *standard-output*))

#<Time Event : PRINT>

(mp:schedule-timer-relative timer 60)

#<Time Event : PRINT>

(mp:unschedule-timer timer)

#<Time Event : PRINT>

(mp:timer-expired-p timer)

T
```

**wait-processing-events***Function*

**Summary** Waits processing events.

**Package** `mp`

**Signature** `wait-processing-events timeout &key wait-reason wait-function  
wait-args => result`

**Arguments** `timeout` A number or `nil`.

`wait-reason` A string.

`wait-function` A function designator.

| Description |                  | <p>The function <code>wait-processing-events</code> does not return until one of two conditions is met:</p> <ul style="list-style-type: none"> <li>• <i>timeout</i> is non-nil and <i>timeout</i> seconds have passed.<br/>In this case, <i>result</i> is <code>nil</code>.</li> <li>• <i>wait-function</i> returns a true value.<br/>In this case, <i>result</i> is <code>t</code>.</li> </ul> <p><i>wait-reason</i> provides the value returned by <code>process-whostate</code> when called on the current process.</p> <p><i>wait-function</i> is called periodically with arguments <i>wait-args</i>. <i>wait-function</i> may be called many times and in several places. Therefore <i>wait-function</i> should be fast and make no assumptions about its dynamic context.</p> <p><code>wait-processing-events</code> processes all events sent to the current process, including system events such as window messages on Microsoft Windows, and objects sent by other processes via <code>process-send</code>. In the latter case, the objects must be lists of the form <code>(function . arguments)</code>, which cause <i>function</i> to be applied to <i>arguments</i> (the values are discarded).</p> <p><code>wait-processing-events</code> is a useful alternative to <code>sleep</code> in a situation where you want to process events to see window updates and so on.</p> |

| Signature   | <code>with-exclusive-lock (sharing-lock &amp;optional whostate timeout) &amp;body body =&gt; results</code>                                                                                                                                                                                                                                                                                                                                                                                                     |
| Arguments   | <p><code>sharing-lock</code> A sharing lock.</p> <p><code>whostate</code> The status of the process while the lock is locked, as seen in the Process Browser.</p> <p><code>timeout</code> A timeout period, in seconds.</p> <p><code>body</code> The forms to execute</p>                                                                                                                                                                                                                                       |
| Values      | <code>results</code> The values returned from evaluating body.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description | The macro <code>with-exclusive-lock</code> is the same as <code>with-lock</code> , except that the lock must be "sharing", that is, created with the argument <code>sharing</code> true in <code>make-lock</code> . It waits until <code>sharing-lock</code> is completely free, that is, the lock is not locked in a sharing mode and is not locked in exclusive mode by another thread. It then locks the lock <code>sharing-lock</code> in exclusive mode, evaluates <code>body</code> and unlocks the lock. |
| Notes       | It is not possible to use an exclusive lock in the scope of a sharing-lock on the same lock, and trying to do it will cause the process to hang. Whether it is possible to use exclusive-lock inside exclusive-lock of the same lock is determined by the <code>recursivelp</code> argument in <code>make-lock</code> .                                                                                                                                                                                         |
| See also    | <code>make-lock</code><br><code>with-lock</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## with-interrupts-blocked

*Macro*

|         |                                         |
|---------|-----------------------------------------|
| Summary | Evaluates code with interrupts blocked. |
| Package | <code>mp</code>                         |

|             |                                                                                                                                     |                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| Signature   | <code>with-interrupts-blocked &amp;body body =&gt; results</code>                                                                   |                                             |
| Arguments   | <i>body</i>                                                                                                                         | Code                                        |
| Values      | <i>results</i>                                                                                                                      | Values returned by evaluating <i>body</i> . |
| Description | Evaluates <i>body</i> with interrupts blocked. This actually expands to<br><br><code>(mp:allowing-block-interrupts t ,@body)</code> |                                             |
|             | which means it also allows you to change the blocking of interrupts.                                                                |                                             |
|             | See the entry for <code>allowing-block-interrupts</code> for full details.                                                          |                                             |
| See also    | <code>allowing-block-interrupts</code>                                                                                              |                                             |

| <b>with-lock</b> |                                                                                          | <i>Macro</i>                                                                        |
|------------------|------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| Summary          | Executes a body of code while holding a lock.                                            |                                                                                     |

| Signature        | <code>with-lock (lock &amp;optional whostate timeout) &amp;body body =&gt; result</code> |                                                                                     |
| Arguments        | <i>lock</i>                                                                              | The lock.                                                                           |
|                  | <i>whostate</i>                                                                          | The status of the process while the lock is locked, as seen in the Process Browser. |
|                  | <i>timeout</i>                                                                           | A timeout period, in seconds.                                                       |
|                  | <i>body</i>                                                                              | The forms to execute.                                                               |
| Values           | <i>result</i>                                                                            | The result of executing <i>body</i> .                                               |

|             |                                                                                                                                                                                                                                                                                                                                            |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <code>with-lock</code> executes <i>body</i> while holding the lock, and unlocks the lock when <i>body</i> exits. This is the recommended way of using locks. The value of <i>body</i> is returned normally. <i>body</i> is not executed if the lock could not be claimed, in which case, <code>with-lock</code> returns <code>nil</code> . |

## with-sharing-lock *Macro*

|             |                                                                                                                                                                                                                     |                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| Summary     | Holds a lock in shared mode while executing a body of code.                                                                                                                                                         |                                                                                     |
| Package     | <code>mp</code>                                                                                                                                                                                                     |                                                                                     |
| Signature   | <code>with-sharing-lock (<i>sharing-lock</i> &amp;optional <i>whostate timeout</i>)<br/>&amp;body <i>body</i> =&gt; <i>results</i></code>                                                                           |                                                                                     |
| Arguments   | <i>sharing-lock</i>                                                                                                                                                                                                 | A sharing lock.                                                                     |
|             | <i>whostate</i>                                                                                                                                                                                                     | The status of the process while the lock is locked, as seen in the Process Browser. |
|             | <i>timeout</i>                                                                                                                                                                                                      | A timeout period, in seconds.                                                       |
|             | <i>body</i>                                                                                                                                                                                                         | The forms to execute                                                                |
| Values      | <i>results</i>                                                                                                                                                                                                      | The values returned from evaluating <i>body</i> .                                   |
| Description | The macro <code>with-sharing-lock</code> is like <code>with-lock</code> , but the lock must be "sharing" and the lock will be locked in shared mode. That means that other threads can also lock it in shared mode. |                                                                                     |

Before locking this waits for the lock to be free of any exclusive lock, but it does not check for other shared mode use of the same lock.

Notes      It is possible to lock for sharing inside the scope of sharing lock and inside the scope of an exclusive lock.

              `with-lock`

## **`without-interrupts`** *Macro*

Summary     Causes any interrupts that occur during the execution of a body of code to be queued, in non-SMP LispWorks only.

Package     `mp`

Signature    `without-interrupts &rest body => result`

Arguments    `body`      The forms to execute while interrupts are queued.

Values        `result`     The result of executing `body`.

Description    While `body` is executing, all interrupts (for example, preemption, keyboard break etc.) are queued. They are executed when `body` exits.

Notes        `without-interrupts` is not supported in SMP LispWorks, that is on Microsoft Windows, Mac OS X, Linux, FreeBSD and x86/x64 Solaris platforms.

Example      To ensure that the seconds and milliseconds slots are always consistent in non-SMP LispWorks, you can use `without-interrupts` within the function which sets them.

```
(defstruct elapsed-time
 seconds
 milliseconds)

(defun update-elapsed-time-atomically
 (elapsed-time seconds milliseconds)
 (mp:without-interrupts
 (setf (elapsed-time-seconds elapsed-time) seconds
 (elapsed-time-milliseconds elapsed-time)
 milliseconds)))
```

See also [without-preemption](#)

## **without-preemption** *Macro*

Summary Identifies forms which should not be preempted during execution, in non-SMP LispWorks only

Package `mp`

Signature `without-preemption &rest body => result`

Arguments `body` The forms to be evaluated atomically.

Values `result` The result of executing `body`.

Description Identifies forms which should not be preempted during execution.

Notes `without-preemption` is not supported in SMP LispWorks, that is on Microsoft Windows, Mac OS X, Linux, FreeBSD and x86/x64 Solaris platforms.

## **yield** *Function*

Summary Allows preemption to happen in low safety code.

| Arguments   | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Values      | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Description | Normally code compiled at safety 0 cannot be preempted because the necessary checks are omitted. This can be overcome by calling <code>yield</code> at regular intervals. Usually there is no need to call this if you use functions from the <code>common-lisp</code> package because these are not compiled at safety 0, but for example if you find that preemption is not working in a loop with no function calls, <code>yield</code> can be useful. Note that <code>process-allow-scheduling</code> also allows preemption, but also checks the wait functions of other processes. |
| See also    | <code>process-allow-scheduling</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## The PARSERGEN Package

This chapter describes symbols available in the **PARSERGEN** package, the Lisp-Works parser generator.

This functionality is discussed in detail in Chapter 17, “The Parser Generator”.

| defparser | Macro                                                                                                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | Creates a parsing function of the given name for the grammar defined.                                                                                                                                                          |
| Package   | <b>parsergen</b>                                                                                                                                                                                                               |
| Signature | <b>defparser name {rule}* =&gt; parsing-function</b><br><b>rule ::= normal-rule   error-rule</b><br><b>normal-rule ::= ((non-terminal {grammar-symbol}*) {form}*)</b><br><b>error-rule ::= ((non-terminal :error) {form}*)</b> |
| Arguments | <b>name</b> The name of the parser.                                                                                                                                                                                            |

The rules define the productions of the grammar and the associated forms define the semantic actions for the rules.

Values      *parsing-function* The symbol name of the parsing function.

Description    **defparser** creates a parsing function of the given name for the grammar defined. The parsing function is defined as if by:

```
(defun <name> (&optional (symbol-to-string
 #'identify)))
```

The *lexer* parameter is a function of no arguments that returns two values: the next grammar token on the input and the associated semantic value.

The optional symbol-to-string function can be used to define a printed representation of the grammar tokens. The function should take a grammar symbol as its single argument and returns an object to be used as a print representation for the grammar token.

For a full description and examples, see Chapter 17, “The Parser Generator”.

## The SERIAL-PORT Package

This chapter describes the symbols available in the **SERIAL-PORT** package.

The Serial Port functionality is loaded into LispWorks by evaluating

```
(require "serial-port")
```

**Note:** this chapter applies only to LispWorks for Windows, and not the UNIX, Linux or Mac OS X platforms.

|           |             | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   |             | Attempts to open the named serial port and return a <b>serial-port</b> object.                                                                                                                                                                                                                                                                                  |
| Package   |             | <b>serial-port</b>                                                                                                                                                                                                                                                                                                                                              |
| Signature |             | <b>open-serial-port</b> <i>name</i> &rest <i>args</i> &key <i>baud-rate</i> <i>data-bits</i> <i>stop-bits</i> <i>parity</i> <i>cts-flow-p</i> <i>dsr-flow-p</i> <i>dtr rts</i> <i>read-interval-timeout</i> <i>read-total-base-timeout</i> <i>read-total-byte-timeout</i> <i>write-total-base-timeout</i> <i>write-total-byte-timeout</i> => <b>serial-port</b> |
| Arguments | <i>name</i> | A string naming a serial port.                                                                                                                                                                                                                                                                                                                                  |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                      |

|             | <b>args</b>                                                                                                                                                                                                                                                                                                                                                                                                                                             | See in the Description below for details of the remaining arguments. |
| Values      | <b>serial-port</b>                                                                                                                                                                                                                                                                                                                                                                                                                                      | A <b>serial-port</b> object.                                         |
| Description | The function <b>open-serial-port</b> attempts to open the serial port <i>name</i> and return a <b>serial-port</b> object.<br><br><i>name</i> is passed directly to <b>Createfile()</b> . For ports COM <i>n</i> where <i>n</i> > 9, you must take care to pass the real port name expected by Windows. At the time of writing this issue is documented at <a href="http://support.microsoft.com/kb/115831">http://support.microsoft.com/kb/115831</a> . |                                                                      |
|             | If any of <i>baud-rate</i> , <i>data-bits</i> , <i>stop-bits</i> and <i>parity</i> are supplied then the corresponding serial port settings are changed. The values of <i>baud-rate</i> and <i>data-bits</i> should each be an appropriate integer. The value of <i>stop-bits</i> should be 1, 1.5 or 2. The value of <i>parity</i> should be one of the keywords <b>:even</b> , <b>:mark</b> , <b>:none</b> , <b>:odd</b> or <b>:space</b> .           |                                                                      |
|             | The arguments <i>cts-flow-p</i> and <i>dsr-flow-p</i> control whether write operations respond to CTS and DSR flow control. A non-nil value means that the corresponding flow control is used.                                                                                                                                                                                                                                                          |                                                                      |
|             | The arguments <i>dtr</i> and <i>rts</i> control whether read operations generate DTR or RTS flow control. If the value is <b>:handshake</b> then the corresponding flow control signal is generated automatically. If the value is <b>nil</b> or <b>t</b> then the initial state of the flow control signal is set and automatic flow control is not used. See <b>set-serial-port-state</b> for manual flow control.                                    |                                                                      |
|             | The argument <i>read-interval-timeout</i> can be used to control the maximum time to wait between each input character. The value <b>:none</b> means that reading will not wait for characters at all, only returning whatever is already in the input buffer                                                                                                                                                                                           |                                                                      |
|             | The arguments <i>read-total-base-timeout</i> and <i>read-total-byte-timeout</i> can be used to control the maximum time to wait for a                                                                                                                                                                                                                                                                                                                   |                                                                      |

sequence of characters. The arguments *write-total-base-timeout* and *write-total-byte-timeout* can be used to control the maximum time to wait when transmitting a sequence of characters. For both reading and writing the timeout is given by the expression:

```
base_timeout + nchars * byte_timeout
```

The default value of each of *read-total-base-timeout*, *read-total-byte-timeout*, *write-total-base-timeout* and *write-total-byte-timeout* is `nil` and this means that the corresponding parameter in the OS is left unchanged and there is zero timeout. Otherwise the value should be a non-negative real number specifying a timeout in seconds.

|------------------------------|-----------------|
| <b>get-serial-port-state</b> | <i>Function</i> |
|------------------------------|-----------------|

Summary      Queries various aspects of the state of a serial port.

Package      `serial-port`

Signature      `get-serial-port-state serial-port keys => state`

Arguments      `serial-port`      A `serial-port` object.

`keys`      A list of keywords.

Values      `state`      A list.

Description      The function `get-serial-port-state` queries various aspects of the state of the serial port associated with `serial-port`.

The argument `keys` should be a list of one or more of the keywords `:dsr` and `:cts`. These cause `get-serial-port-state` to check the DSR and CTS lines respectively.

The result `state` is a list giving the state of each line in the same order as they appear in the argument `keys`.

|                    |              |
|--------------------|--------------|
| <b>serial-port</b> | <i>Class</i> |
|--------------------|--------------|

Summary      The class of objects representing serial ports.

Package      `serial-port`

Description      The class `serial-port` is the class of objects representing serial ports. These are constructed by `open-serial-port` - do not create them directly.

| Description                  | The function <code>read-serial-port-char</code> reads and returns a character from the serial port associated with <code>serial-port</code> .<br><br>A timeout will occur if the character is not available before the read timeout (as specified by values given when the serial port was opened by <code>open-serial-port</code> ).<br><br>When a timeout occurs, if <code>timeout-error-p</code> is non-nil, then an error of type <code>serial-port-timeout</code> is signalled, otherwise <code>timeout-char</code> is returned. The default value of <code>timeout-error-p</code> is <code>t</code> . |

|--------------------------------------|---------------------------------------------------------------------|------------------------------------|
| Summary                              | Checks whether a character is available on a serial port.           |                                    |
| Package                              | <code>serial-port</code>                                            |                                    |
| Signature                            | <code>serial-port-input-available-p serial-port =&gt; result</code> |                                    |
| Arguments                            | <i>serial-port</i>                                                  | A <code>serial-port</code> object. |
| Values                               | <i>result</i>                                                       | A boolean.                         |

Description      The function `serial-port-available-p` checks the serial port associated with `serial-port` to see if a character is available. `result` is `t` if input is available, and `nil` otherwise.

## **set-serial-port-state** *Function*

Summary      Changes various aspects of the state of a serial port.

Package      `serial-port`

Signature      `set-serial-port-state serial-port &key dtr rts break`

Arguments      `serial-port`      A `serial-port` object.

`dtr`      A boolean.

`rts`      A boolean.

`break`      A boolean.

Description      The function `set-serial-port-state` changes various aspects of the state of the serial port associated with `serial-port`.

The argument `dtr`, if supplied, controls the DTR line. A true value means set and `nil` means clear. If `dtr` is not supplied, the state is unchanged.

The argument `rts` controls the RTS line in the same way.

The argument `break` controls the break state of the data line in the same way.

## **wait-serial-port-state** *Function*

Summary      Waits for some aspect of the state of a serial port to change.

Package      `serial-port`

| Arguments | <code>char</code>                                                                             | A character.                       |
|           | <code>serial-port</code>                                                                      | A <code>serial-port</code> object. |
|           | <code>timeout-error-p</code>                                                                  | A boolean.                         |
| Values    | <code>char</code>                                                                             | A character.                       |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>write-serial-port-char</code> writes the character <i>char</i> to the serial port associated with <i>serial-port</i> , and returns <i>char</i> .<br><br>A timeout will occur if the character cannot be written before the write timeout (as specified by values given when the serial port was opened by <code>open-serial-port</code> ).<br><br>When a timeout occurs, if <i>timeout-error-p</i> is non-nil, then an error of type <code>serial-port-timeout</code> is signalled, otherwise <code>nil</code> is returned. The default value of <i>timeout-error-p</i> is <code>t</code> . |

| <i>start, end</i>                            | Bounding index designators for <i>string</i> .                                                                                                                                                                                                                                                                                                            |               |           |                    |                                    |                        |            |                   |                                                |
| Values                                       | <i>result</i><br>The string <i>string</i> or <code>nil</code> .                                                                                                                                                                                                                                                                                           |               |           |                    |                                    |                        |            |                   |                                                |
| Description                                  | The function <code>write-serial-port-string</code> writes characters from the subsequence of <i>string</i> bounded by <i>start</i> and <i>end</i> to the serial port associated with <i>serial-port</i> .<br><br>The default values of <i>start</i> and <i>end</i> are 0 and <code>nil</code> (interpreted as the length of <i>string</i> ) respectively. |               |           |                    |                                    |                        |            |                   |                                                |

If the characters are successfully written then *string* is returned.

A timeout will occur if the characters cannot be written before the write timeout (as specified by values given when the serial port was opened by `open-serial-port`).

When a timeout occurs, if *timeout-error-p* is non-nil, then an error of type `serial-port-timeout` is signalled, otherwise `nil` is returned. The default value of *timeout-error-p* is `t`.

## The SQL Package

This chapter describes the symbols available in the `sql` package which implements Common SQL. You should use this chapter in conjunction with Chapter 19, “Common SQL”. In particular that chapter contains more information about the Oracle LOB interface (that is, those functions with names beginning `sql:ora-lob-`).

On Microsoft Windows, Linux, x86/x64 Solaris, FreeBSD and Mac OS X, Common SQL is included only in LispWorks Enterprise Edition.

| <b>add-sql-stream</b> |                     | <i>Function</i>                                                              |
|-----------------------|---------------------|------------------------------------------------------------------------------|
| Summary               |                     | Adds a stream to the broadcast list for SQL commands or results traffic.     |
| Package               |                     | <code>sql</code>                                                             |
| Signature             |                     | <code>add-sql-stream stream &amp;key type database -&gt; added-stream</code> |
| Arguments             | <code>stream</code> | A stream, or <code>t</code> .                                                |
|                       | <code>type</code>   | A keyword.                                                                   |

|             |                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>database</i>     | A database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Values      | <i>added-stream</i> | The argument <i>stream</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description |                     | <p>The function <code>add-sql-stream</code> adds the stream <i>stream</i> to the list of streams which receive SQL commands traffic or results traffic.</p> <p>To add <code>*standard-output*</code> to the list, pass <i>stream t</i>.</p> <p>The argument <i>type</i> is one of <code>:commands</code>, <code>:results</code> or <code>:both</code>, and determines whether a stream for commands traffic, results traffic, or both is added.</p> <p>The argument <i>type</i> has a default value of <code>:commands</code>. The <i>database</i> is the value of <code>*default-database*</code> by default.</p> |

| Values      | <i>datatype</i> | A keyword or list denoting a vendor-specific type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description |                 | <p>The function <code>attribute-type</code> returns the type of the attribute specified by <i>attribute</i> in the table given by <i>table</i>. The database, in which <i>table</i> is found, has a default value of <code>*default-database*</code>.</p> <p>If <i>owner</i> is <code>nil</code>, only user-owned attributes are considered. This is the default.</p> <p>If <i>owner</i> is <code>:all</code>, all attributes are considered.</p> <p>If <i>owner</i> is a string, this denotes a username and only attributes owned by <i>owner</i> are considered.</p> <p><i>datatype</i> demotes a vendor-specific type. Examples in a MS Access database are <code>:integer</code>, <code>:longchar</code> and <code>:datetime</code>. When <i>datatype</i> is a list, the second element is the length of the type, for example <code>(:varchar 255)</code>.</p> |
| Example     |                 | To print the type of every attribute in the database, do                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Description         | <p>The function <code>cache-table-queries</code> provides per-table control on the caching in a particular database connection of attribute type information using during update operations.</p> <p>If <i>table</i> is a string, it is the name of the table for which caching is to be altered. If <i>table</i> is t, then the <i>action</i> applies to all tables. If <i>table</i> is :default, then the default caching action is set for those tables which do not have an explicit setting.</p> <p><i>database</i> specifies the database connection, its default value is the value of *default-database*.</p> <p><i>action</i> specifies the caching action. The value t means cache the attribute type information. The value nil means do not cache the attribute type information. If <i>table</i> is :default, the setting applies to all tables which do not have an explicit setup.</p> <p>The value :flush means remove any existing cache for <i>table</i> in <i>database</i>, but continue to cache.</p> <p><code>cache-table-queries</code> should be called with <i>action</i> :flush when the attribute specifications in <i>table</i> have changed.</p> |              |                                         |                 |             |               |                   |

| Values                               | <code>nil</code>                                                                                                                                                                                                 |                 |
| Description                          | The function <b>commit</b> commits changes made to the database specified by <i>database</i> , which is <b>*default-database*</b> by default.                                                                    |                 |
| Example                              | This example changes records in a database, and uses <b>commit</b> to make those changes permanent.                                                                                                              |                 |

```
(insert-records :into [emp]
 :attributes '(x y z)
 :values '(a b c))
(update-records [emp]
 :attributes [dept]
 :values 50
 :where [= [dept] 40])
(delete-records :from [emp]
 :where [> [salary] 300000])
(commit)
```

|             | <i>default-table-type</i>          | A string, the keyword<br><code>:support-transactions</code> , or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|             | <i>default-table-extra-options</i> | A string or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | <i>date-string-format</i>          | A string, or the keyword <code>:standard</code> , or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|             | <i>sql-mode</i>                    | A string or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | <i>prefetch-rows-number</i>        | An integer or the keyword <code>:default</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | <i>prefetch-memory</i>             | An integer or the keyword <code>:default</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Values      | <i>database</i>                    | A database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Description |                                    | <p>The function <code>connect</code> opens a connection to a database of type <i>database-type</i>.<br/>The allowed values for <i>database-type</i> are <code>:odbc</code>, <code>:odbc-driver</code>, <code>:mysql</code>, <code>:postgresql</code>, <code>:oracle8</code> and <code>:oracle</code>, though not all of these are supported on some platforms. See “Supported databases” on page 225 for details of per-platform database support.</p> <p>The default for <i>database-type</i> is the value of <code>*default-database-type*</code>.</p> <p><code>connect</code> sets the variable <code>*default-database*</code> to an instance of the database opened, and returns that instance.</p> <p>If <i>connection-spec</i> is a list it is interpreted as a plist of keywords and values. Some of the keywords are <i>database-type</i> specific, see the documentation for each database. General keywords are:</p> <ul style="list-style-type: none"><li><code>:username</code> User name</li><li><code>:password</code> Password</li></ul> |

**:connection** A specification of the connection. In general, this is supposed to be sufficient information (other than the username and password) to open a connection. The precise meaning varies according to the *database-type*.

If *connection-spec* is a string, it is interpreted canonically as:

*username/password@connection*

where *connection* can be omitted along with the '@' in cases when there is a default connection, *password* can be omitted along with the preceding '/', and *username* can be omitted if there is a default user. For example, if you have an Oracle user matching the current Unix username and that does not need a password to connect, you can call

```
(connect "/")
```

Specific *database-types* may allow more elaborate syntax, but conforming to the pattern above. See the section “Initialization” on page 227 for details.

Additionally for *database-types* **:odbc** and **:odbc-driver**, if *connection-spec* does not include the '@' character then the string is interpreted in a special way, for backward compatibility with LispWorks 4.4 and earlier versions. See the section “Connecting to ODBC” on page 230 for details.

The argument *if-exists* modifies the behavior of **connect** as follows:

**:new** Makes a new connection even if connections to the same database already exist.

**:warn-new** Makes a new connection but warns about existing connections.

**:error** Makes a new connection but signals an error for existing connections.

**:warn-old** Selects old connection if one exists (and warns) or makes a new one.

*This chapter applies to the Enterprise Edition only*

**:old** Selects old connection if one exists or makes a new one.

The default value of *if-exists* is the value of **\*connect-if-exists\***.

*interface* is used if **connect** needs to display a dialog to ask the user for username and password. If *interface* is a CAPI element, this is used. If *interface* is any other value (the default value is **nil**), and **connect** is called in a process which is associated with a CAPI interface, then this CAPI interface is used. *interface* has been added because dialogs asking for passwords can fail otherwise. This depends on the driver that the datasource uses: the problem has only been observed using MS SQL on Microsoft Windows.

*name* can be passed to explicitly specify the name of the connection. If *name* is supplied then it is used as-is for the connection name. Therefore it can be found by another call to **connect** and calls to **find-database**. Connection names are compared with **equalp**. If *name* is not supplied, then a unique database name is constructed from *connection-spec* and a counter.

**Note:** all the Common SQL functions that accept the keyword argument **:database** use **find-database** to find the database if the given value is not a database. Therefore these functions can now find only databases that were opened with an explicit *name*:

```
(connect ... :name name ...)
```

*encoding* specifies the encoding to use in the connection. The value should be a keyword naming an acceptable encoding, or **nil** (the default). The value **:unicode** is accepted for all *database-types*, and this will try to make a connection that can support sending and retrieving double-byte string values. Other values are *database-type* specific:

`:mysql` If *encoding* is `nil` or `:default` then the encoding is chosen according to the default character set of the connection (if available) and if that fails the encoding `:utf-8` is used. The other recognised values of *encoding* are `:unicode`, `:utf-8`, `:ascii`, `:latin-1`, `:euc` and `:sjis`.

`:unicode` uses `:utf-8` internally.

`:postgresql` If *encoding* is `nil` or `:default` LispWorks does not set anything in the connection. If the connection character set is `SQL_ASCII`, LispWorks uses `:latin-1` to convert to and from Lisp strings, otherwise it uses `:utf-8`.

If *encoding* is one of the keywords listed below, LispWorks uses it as the external format for converting to and from Lisp strings, and LispWorks also sets the connection character set to the corresponding string:

| Keyword               | character-set          | alias                   |
|-----------------------|------------------------|-------------------------|
| <code>:utf-8</code>   | UTF-8                  | <code>:unicode</code>   |
| <code>:latin-1</code> | <code>SQL_ASCII</code> |                         |
| <code>:ascii</code>   | <code>SQL_ASCII</code> |                         |
| <code>:gbk</code>     | GBK                    |                         |
| <code>:euc-jp</code>  | EUC_JP                 | <code>:euc</code>       |
| <code>:sjis</code>    | SJIS                   | <code>:shift-jis</code> |

An alias maps to the corresponding keyword.

In addition, *encoding* can be a string or a cons of a keyword and a string. If it is a string LispWorks uses `:utf-8` as the external format, and sets the connection character set to the string. If it is a cons, the keyword (the car) is used as the external format, and the string (cdr) is used to set the character set.

*This chapter applies to the Enterprise Edition only*

See "character set support" in the PostgreSQL manual for known character sets.

**:oracle** The only recognised values of *encoding* are **nil** and **:unicode**.

**:oracle8** *encoding* is ignored.

**:odbc** or **:odbc-driver**

The valid values of *encoding* are **:unicode** or **nil**. When *encoding* is **nil** it uses the default multibyte encoding.

*signal-rollback-errors* controls what happens when an attempted **rollback** causes an error, for databases that do not support rollback properly (for example MySQL with the default settings). For *database-types* other than **:mysql** *signal-rollback-errors* is ignored and such an error is always signalled. For *database-type* **:mysql** *signal-rollback-errors* is interpreted as follows:

**nil** Ignore the error.

**:default** If *default-table-type* is **:support-transactions**, "innodb" or "bdb", then rollback errors are signalled. Otherwise rollback errors are not signalled.

### Function designator

The function *signal-rollback-errors* should take two arguments: the database object and a string (for an error message). The function is called when a rollback signalled an error.

The default value of *signal-rollback-errors* is **:default**.

*default-table-type* specifies the default value of the **:type** argument to **create-table**. See **create-table** for details. The default value of *default-table-type* is **nil**.

*default-table-extra-options* specifies the default value of the **:extra-options** argument to **create-table**. See **create-**

`table` for details. The default value of `default-table-extra-options` is `nil`.

`date-string-format` specifies which format to use to represent dates. If the value is a string, it should be appropriate for the `database-type`. The value `:standard` means that the standard SQL date format is used. If the value is `nil` (the default), then the date format is not changed. Currently only `database-type :oracle` uses the value of `date-string-format`, and in this case it must be a valid date format string for Oracle.

`sql-mode` specifies the mode of the SQL connection for `database-type :mysql`. By default (that is, when `sql-mode` is not supplied) `connect` sets the mode of the connection to ANSI, by executing this statement:

```
"set sql_mode='ansi'"
```

`sql-mode` can be supplied as `nil`, in which case no statement is executed. Otherwise it should be a string which is a valid setting for `sql_mode`, and then `connect` executes the statement:

```
set sql_mode='sql-mode'
```

When `database-type` is not `:mysql`, `sql-mode` is ignored.

`prefetch-rows-number` and `prefetch-memory` are used when `database-type` is `:oracle`, and specify the amount of data to prefetch when performing queries. `prefetch-rows-number` is the number of rows to prefetch, with default value 100. `prefetch-memory` is the maximum number of bytes to prefetch, with default value `#x100000`. `prefetch-rows-number` and `prefetch-memory` can both also have the value `:default`, which allows the database to choose the amount to prefetch.

|                    |                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Compatibility note | LispWorks 4.4 (and previous versions) use <code>connection-spec</code> passed to <code>connect</code> as the database name. <code>connect</code> checks if a connection with this name already exists (according to the value of <code>if-exists</code> ). <code>find-database</code> can be used to find a database using this name. |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

*This chapter applies to the Enterprise Edition only*

LispWorks 5.0 (and later versions) does not use *connection-spec* as the name. Instead, by default it generates a name from the *connection-spec*. The name is intended to be unique (by including a counter). Thus normally `connect` will not find an existing connection even if it is called again with identical value of *connection-spec*.

**Example** The following example connects LispWorks to the `info` database.

```
(connect "info")
```

The next example connects to the ODBC database `personnel` using the username "admin" and the password "secret".

```
(connect "personnel/admin/secret" :database-type :odbc)
```

The next example opens a connection to MySQL which treats quotes as in ANSI but does not set other ANSI features:

```
(sql:connect "me/mypassword/mydb"
 :sql-mode "ANSI_QUOTES")
```

## \*`connect-if-exists`\*

*Variable*

**Summary** The default value for the *if-exists* keyword of the `connect` function.

**Package** `sql`

|                        |                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Initial Value          | <code>:error</code>                                                                                                                                                               |
| Description            | The variable <code>*connect-if-exists*</code> is the default value for the <code>if-exists</code> keyword of the <code>connect</code> function. It can take the following values: |
| <code>:new</code>      | Instructs <code>connect</code> to make a new connection even if connections to the same database already exist.                                                                   |
| <code>:warn-new</code> | Instructs <code>connect</code> to make a new connection but warn about existing connections.                                                                                      |
| <code>:error</code>    | Instructs <code>connect</code> to make a new connection but signal an error for existing connections.                                                                             |
| <code>:warn-old</code> | Instructs <code>connect</code> to select an old connection if one exists (and warns) or make a new one.                                                                           |
| <code>:old</code>      | Instructs <code>connect</code> to select an old connection if one exists or make a new one.                                                                                       |
| See also               | <code>connect</code>                                                                                                                                                              |

| <b>connected-databases</b> |                            | <i>Function</i>                                                                                          |
|----------------------------|----------------------------|----------------------------------------------------------------------------------------------------------|
| Summary                    |                            | Returns a list of connected databases.                                                                   |
| Package                    |                            | <code>sql</code>                                                                                         |
| Signature                  |                            | <code>connected-databases =&gt; database-list</code>                                                     |
| Arguments                  |                            | None.                                                                                                    |
| Values                     | <code>database-list</code> | A list of connected databases.                                                                           |
| Description                |                            | The function <code>connected-databases</code> returns a list of the databases LispWorks is connected to. |

## create-index *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Creates an index for a table.                                                                                                                                                                                                                                                                                                                                                                                                       |
| Package     | <b>sql</b>                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Signature   | <b>create-index name &amp;key on unique attributes database =&gt;</b>                                                                                                                                                                                                                                                                                                                                                               |
| Arguments   | <b>name</b> The name of the index.<br><b>on</b> The name of a table.<br><b>unique</b> A boolean.<br><b>attributes</b> A list of attributes.<br><b>database</b> A database.                                                                                                                                                                                                                                                          |
| Values      | None.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description | The function <b>create-index</b> creates an index called <i>name</i> on the table specified by <i>on</i> . The attributes of the table to index are given by <i>attributes</i> . Setting <i>unique</i> to t includes UNIQUE in the SQL index command, specifying that the columns indexed must contain unique values.<br><br>The default value of <i>unique</i> is nil. The default value of <i>database</i> is *default-database*. |
| Example     | ( <b>create-index [manager]</b><br><b>:on [emp] :unique t :attributes '([ename] [sal])'</b> )                                                                                                                                                                                                                                                                                                                                       |

| Description          | <p>The function <b>create-table</b> creates a table called <i>name</i> and defines its columns and other properties with <i>description</i>. The argument <i>description</i> is a list containing lists of attribute-name and type information pairs.</p> <p>The default value of <i>database</i> is <b>*default-database*</b>.</p> <p><i>type</i> and <i>extra-options</i> are treated in a <i>database-type</i> specific way. Currently only <i>database-type</i> <b>:mysql</b> uses these options, as follows.</p> <p>If <i>type</i> is not supplied, it defaults to the value (if any) of <i>default-table-type</i> that was supplied to <b>connect</b>. If <i>extra-options</i> is not supplied, it defaults to the value (if any) of <i>default-table-extra-options</i> that was supplied to <b>connect</b>.</p> |             |                        |                    |                       |                 |             |             |                                                                           |                      |                          |

*This chapter applies to the Enterprise Edition only*

*type*, if non-nil, is used as argument to TYPE in the SQL statement:

```
create table MyTable (column-specs) TYPE = type
```

except that if *type* is :support-transactions then `create-table` will attempt to make tables that support transactions, by using the type `innodb`.

*extra-options* (if non-nil) is appended in the end of this SQL statement.

When *database-type* is not :mysql, *type* and *extra-options* are ignored.

#### Example

The following code:

```
(create-table [manager]
 '(([id] (char 10) not-null)
 ([salary] (number 8 2))))
```

is equivalent to the following SQL:

```
CREATE TABLE MANAGER
 (ID CHAR(10) NOT NULL, SALARY NUMBER(8,2))
```

#### See also

```

default-database
drop-table
```

## create-view

## *Function*

#### Summary

Creates a view using a specified query.

#### Package

`sql`

#### Signature

```
create-view name &key as column-list with-check-option
database =>
```

#### Arguments

*name*

The view to be created.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>as</b>                       | A SQL query statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>column-list</b>              | A list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b><i>with-check-option</i></b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                 | A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>database</b>                 | A database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Values</b>                   | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b>              | <p>The function <code>create-view</code> creates a view called <i>name</i> using the <code>as</code> query and the optional <code>column-list</code> and <code>with-check-option</code>. The <code>column-list</code> argument is a list of columns to add to the view. The <code>with-check-option</code> adds <code>WITH CHECK OPTION</code> to the resulting SQL.</p> <p>The default value of <code>with-check-option</code> is <code>nil</code>. The default value of <code>database</code> is <code>*default-database*</code>.</p> |
| <b>Example</b>                  | This example creates the view <code>manager</code> with the records in the employee table whose department is 50.                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                 | <pre>(create-view [manager] :as [select [*]                                 :from [emp]                                 :where [= [dept] 50]])</pre>                                                                                                                                                                                                                                                                                                                                                                                    |

**\*default-database\*** *Variable*

Summary      The default database in database operations.

Package      `sql`

Initial Value      `nil`

Description      The variable `*default-database*` is set by `connect` and specifies the default database to be used for database operations.

See also      `connect`

**\*default-database-type\*** *Variable*

Summary      Specifies the default type of database.

Package      `sql`

Initial Value      `nil`

Description      The variable `*default-database-type*` specifies the default type of database. You can set this or it is initialized by the `initialize-database-type` function.

LispWorks supports the values shown in “Supported databases” on page 225.

See also      `initialize-database-type`

**\*default-update-objects-max-len\*** *Variable*

Summary      The default maximum number of objects supplying data for a query when updating remote joins.

*This chapter applies to the Enterprise Edition only*

| Values       | <code>class</code>                                                                                                                                                                                                                                                                                                                                                                                  | The defined class.                           |  |
| Slot Options | The slot options for <code>def-view-class</code> are <code>:db-kind</code> and <code>:db-info</code> . In addition the slot option <code>:type</code> is treated specially for View Classes.<br><br><code>:db-kind</code> may be one of <code>:base</code> , <code>:key</code> , <code>:join</code> , or <code>:virtual</code> . The default is <code>:base</code> . Each value is described below: |                                              |  |

|                 |                                                                                                                                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>:base</b>    | This indicates that this slot corresponds to an ordinary attribute of the database view. You can name the database attribute by using the keyword <b>:column</b> . By default, the database attribute is named by the slot.                             |
| <b>:key</b>     | This indicates that this slot corresponds to part of the unique key for this view. A <b>:key</b> slot is also a <b>:base</b> slot. All View Classes must have <b>:key</b> fields that uniquely distinguish the instances, to maintain object identity.  |
|                 | To specify a key which spans multiple slots, each of the slots should have <b>:db-kind :key</b> . The underlying requirement is that tuples of the form (key1 ... keyN) are unique. The <b>:db-kind :key</b> slots do not need to be keys in the table. |
| <b>:join</b>    | This indicates that this slot corresponds to a join. A slot of this type will contain View Class objects.                                                                                                                                               |
| <b>:virtual</b> | This indicates that this slot is an ordinary CLOS slot not associated with a database column.                                                                                                                                                           |

A join is defined by the slot option **:db-info**, which takes a list. Items in the list may be:

**:join-class class-name**

This is the class to join on.

**:home-key slot-name**

This is the slot of the defining class to be a subject for the join. The argument *slot-name* may be an element or a list of elements, where elements can be symbols, **nil**, strings, integers or floats.

*This chapter applies to the Enterprise Edition only*

**:foreign-key** *slot-name*

This is the name of the slot of the **:join-class** to be a subject for the join. The *slot-name* may be an element or a list of elements, where elements can be symbols, **nil**, strings, integers or floats.

**:target-slot** *target-slot*

This is the name of a **:join** slot in **:join-class**. This is optional and is only specified if you want the defining slot to contain instances of this target slot as opposed to those of **:join-class**. The actual behavior depends on the value of *set*. An example of its usage is when the **:join-class** is an intermediate class and you are really only interested in it as a route to the **:target-slot**.

**:retrieval** *retrieval-time*

*retrieval-time* can be **:deferred**, which defers filling this slot from the database until the slot itself is accessed. This is the default value.

*retrieval-time* can alternatively be **:immediate** which generates the join SQL for this slot whenever a query is generated on the class. In other words, this is an intermediate class only, which is present for the purpose of joining two entities of other classes together. When *retrieval-time* is **:immediate**, then *set* is **nil**.

**:set** *set*

When *set* is **t** and *target-slot* is defined, the slot will contain a list of pairs (*target-value join-instance*) where *target-value*

is the value of the target slot and *join-instance* is the corresponding instance of the join class.

When *set* is *t* and *target-slot* is undefined, the slot will contain a list of instances of the join class.

When *set* is *nil* the slot will contain a single instance.

The default value of *set* is *t*.

The syntax for `:home-key` and `:foreign-key` means that an object from a join class will only be included in the join slot if the values from *home-key* are *equal* to the values in *foreign-key*, in order. These values are calculated as follows: if the element in the list is a symbol it is taken to be a slot name and the value of the slot is used, otherwise the element is taken to be the value. See the second example below.

The `:type` slot option is treated specially for View Classes. There is a need for stringent type-checking in View Classes because of the translation into database data, and therefore `:type` is mandatory for slots with `:db-kind :base` or `:key`. Some methods are provided for type checking and type conversion. For example, a `:type` specifier of `(string 10)` in SQL terms means allow a character type value with length of less than or equal to 10. The following Lisp types are accepted for *type*, and correspond to the SQL type shown:

|                                 |            |
|---------------------------------|------------|
| <code>(string n)</code>         | CHAR(n)    |
| <code>integer</code>            | INTEGER    |
| <code>(integer n)</code>        | INTEGER(n) |
| <code>float</code>              | FLOAT      |
| <code>(float n)</code>          | FLOAT(n)   |
| <code>sql:universal-time</code> |            |
|                                 | TIMESTAMP  |

*This chapter applies to the Enterprise Edition only*

Class Options `def-view-class` recognizes the following class options in addition to the standard class options defined for `defclass`:

`(:base-table table-name)`

The slots of the class *name* will be read from the table *table-name*. If you do not specify the `:base-table` option, then *table-name* defaults to the name of the class.

Description The macro `def-view-class` creates a class called *name* which maps onto a database view. Such a class is called a View Class.

The macro `def-view-class` extends the syntax of `defclass` to allow special *base slots* to be mapped onto the attributes of database views (presently single tables). When a `select` query that names a View Class is submitted, then the corresponding database view is queried, and the slots in the resulting View Class instances are filled with attribute values from the database.

If *superclasses* is `nil` then `standard-db-object` automatically becomes the superclass of the newly-defined View Class. If *superclasses* is `nil`, it must include `standard-db-object`.

Examples The following example shows a class corresponding to the traditional *employees* table, with the employee's department given by a join with the *departments* table.

```
(def-view-class employee (standard-db-object)
 ((employee-number :db-kind :key
 :column empno
 :type integer)
 (employee-name :db-kind :base
 :column ename
 :type (string 20)
 :accessor employee-name)
 (employee-department :db-kind :base
 :column deptno
 :type integer
 :accessor employee-department)
 (employee-job :db-kind :base
 :column job
 :type (string 9))
 (employee-manager :db-kind :base
 :column mgr
 :type integer)
 (employee-location :db-kind :join
 :db-info (:join-class department
 :retrieval :deferred
 :set nil
 :home-key
 employee-department
 :foreign-key
 department-number
 :target-slot
 department-loc)
 :accessor employee-location)
 (:base-table emp))
```

The following example illustrates how elements or lists of elements can follow `:home-key` and `:foreign-key` in the `:db-info` slot option.

```
(def-view-class flex-schema ()
 ((name :type (string 8) :db-kind :key)
 (description :type (string 256)))
 (classes :db-kind :join
 :db-info (:home-key name
 :foreign-key schema-name
 :join-class flex-class
 :retrieval :deferred)))
 (:base-table flex_schema))
```

*This chapter applies to the Enterprise Edition only*

```
(def-view-class flex-class ()
 ((schema-name :type (string 8) :db-kind :key
 :column schema_name)
 (name :type (string 32) :db-kind :key)
 (base-name :type (string 64) :column base_name)
 (super-classes :db-kind :join
 :db-info (:home-key
 (schema-name name)
 :foreign-key
 (schema-name class-name)
 :join-class
 flex-superclass
 :retrieval :deferred))
 (schema :db-kind :join
 :db-info (:home-key schema-name
 :foreign-key name
 :join-class flex-schema
 :set nil))
 (properties :db-kind :join
 :db-info (:home-key (schema-name name ""))
 :foreign-key
 (schema-name class-name slot-name)
 :join-class flex-property
 :retrieval :deferred)))
 (:base-table flex_class))

(def-view-class flex-slot ()
 ((schema-name :type (string 8) :db-kind :key
 :column schema_name)
 (class-name :type (string 32) :db-kind :key
 :column class_name)
 (name :type (string 32) :db-kind :key)
 (class :db-kind :join
 :db-info (:home-key (schema-name class-name)

 :join-class flex-class
 :set nil))
 (properties :db-kind :join
 :db-info (:home-key
 (schema-name class-name name)
 :foreign-key
 (schema-name class-name slot-name)
 :join-class flex-property
 :retrieval :deferred)))
 (:base-table flex_slot))
```

```
(def-view-class flex-property ()
 ((schema-name :type (string 8) :db-kind :key
 :column schema_name)
 (class-name :type (string 32) :db-kind :key
 :column class_name)
 (slot-name :type (string 32) :db-kind :key
 :column slot_name)
 (property :type (string 32) :db-kind :key)
 (values :db-kind :join
 :db-info (:home-key
 (schema-name class-name
 slot-name property)
 :foreign-key
 (schema-name class-name
 slot-name property)
 :join-class flex-property-value
 :retrieval :deferred)))
 (:base-table flex_property))

(def-view-class flex-property-value ()
 ((schema-name :type (string 8) :db-kind :key
 :column schema_name)
 (class-name :type (string 32) :db-kind :key
 :column class_name)
 (slot-name :type (string 32) :column slot_name)
 (property :type (string 32) :db-kind :key)
 (order :type integer)
 (value :type (string 128)))
 (:base-table flex_property_value))
```

## destroy-prepared-statement *Function*

Summary      Destroys a prepared-statement and frees its resources.

Package      `sql`

Signature      `destroy-prepared-statement prepared-statement => nil`

Arguments      *prepared-statement*  
                  A prepared-statement.

Description      The function `destroy-prepared-statement` destroys the prepared-statement *prepared-statement* and frees its resources. It should be called before closing the database associated with the prepared-statement. A destroyed prepared-statement can be reused by calling `set-prepared-statement-variables` with a new database.

`destroy-prepared-statement` always returns `nil`.

`set-prepared-statement-variables`

## disable-sql-reader-syntax *Function*

Summary      Turns off square bracket syntax.

Package      `sql`

Signature      `disable-sql-reader-syntax =>`

Arguments      None.

| Description | The function <code>disable-sql-reader-syntax</code> turns off square bracket syntax and sets state so that <code>restore-sql-reader-syntax-state</code> will make the syntax disabled if it is consequently enabled. |

| Values      | <code>success</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | A boolean.  |
| Description | <p>The function <code>disconnect</code> closes a connection to a database specified by <code>database</code>. If successful, <code>success</code> is <code>t</code> and if only one other connection exists, <code>*default-database*</code> is reset.</p> <p>The default value for <code>database</code> is <code>*default-database*</code>. If <code>database</code> is a database object, then it is used directly. Otherwise, the list of connected databases is searched to find one with <code>database</code> as its connection specifications (see <code>connect</code>). If no such database is found, then if <code>error</code> and <code>database</code> are both non-nil an error is signaled, otherwise <code>disconnect</code> returns <code>nil</code>.</p> |             |

*This chapter applies to the Enterprise Edition only*

Example      `(disconnect :database "test")`

|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| Summary     | Repeatedly binds a set of variables to the results of a query, and executes a body of code using the bound variables.                                                                                                                                                                                    |       |
| Package     | sql                                                                                                                                                                                                                                                                                                      |       |
| Signature   | <pre>do-query ((&amp;rest args) query &amp;key database not-inside-transaction get-all) &amp;body body =&gt;</pre>                                                                                                                                                                                       |       |
| Arguments   | <p><i>args</i> A set of variables.</p> <p><i>query</i> A database query or a prepared-statement containing a query.</p> <p><i>database</i> A database.</p> <p><i>not-inside-transaction</i> A generalized boolean.</p> <p><i>get-all</i> A generalized boolean.</p> <p><i>body</i> A Lisp code body.</p> |       |
| Values      | None.                                                                                                                                                                                                                                                                                                    |       |
| Description | The macro <code>do-query</code> repeatedly executes <i>body</i> within a binding of <i>args</i> on the attributes of each record resulting from <i>query</i> . <code>do-query</code> returns no values.                                                                                                  |       |

The default value of *database* is \*default-database\*.

*not-inside-transaction* and *get-all* may be useful when fetching many records through a connection with *database-type* :mysql. Both of these arguments have default value nil. See the section “Special considerations for iteration functions and macros” on page 260 for details.

|         |                                                                                                                                                                                                                                               |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example | The following code repeatedly binds the result of selecting an entry in <code>ename</code> from the table <code>emp</code> to the variable <code>name</code> , and then prints <code>name</code> using the Lisp function <code>print</code> . |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
(do-query ((name) [select [ename] :from [emp]])
 (print name))
```

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <b>drop-view</b> deletes view from <i>database</i> .<br>The default value of <i>database</i> is <b>*default-database*</b> .   |
| Notes       | <b>DROP VIEW</b> is not implemented in MS Access SQL, so <b>drop-view</b> does not work with that database. Use <b>drop-table</b> instead. |
| See also    | <b>create-view</b><br><b>*default-database*</b><br><b>drop-index</b><br><b>drop-table</b>                                                  |

## drop-view-from-class *Function*

|             |                                                                                                                                                                                                                           |             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| Summary     | Deletes a view from a database based on a class defining the view.                                                                                                                                                        |             |
| Package     | <b>sql</b>                                                                                                                                                                                                                |             |
| Signature   | <b>drop-view-from-class</b> <i>class</i> & <b>key</b> <i>database</i> =>                                                                                                                                                  |             |
| Arguments   | <i>class</i>                                                                                                                                                                                                              | A class.    |
|             | <i>database</i>                                                                                                                                                                                                           | A database. |
| Values      | None.                                                                                                                                                                                                                     |             |
| Description | The function <b>drop-view-from-class</b> deletes a view or base table from <i>database</i> based on <i>class</i> which defines that view. The argument <i>database</i> has a default value of <b>*default-database*</b> . |             |
| See also    | <b>create-view-from-class</b><br><b>*default-database*</b><br><b>drop-view</b>                                                                                                                                            |             |

| Summary                | Executes a SQL expression.                                                                      |
| Package                | <code>sql</code>                                                                                |
| Signature              | <code>execute-command sql-exp &amp;key database =&gt;</code>                                    |
| Arguments              | <code>sql-exp</code> Any SQL statement other than a query.<br><code>database</code> A database. |
| Values                 | None.                                                                                           |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>execute-command</code> executes the SQL command specified by <code>sql-exp</code> for the database specified by <code>database</code>, which has a default value of <code>*default-database*</code>. The argument <code>sql-exp</code> may be any SQL statement other than a query.</p> <p>To run a stored procedure, pass an appropriate string. The call to the procedure needs to be wrapped in a PL/SQL <code>BEGIN END</code> pair, for example:</p> <pre>(sql:execute-command   "BEGIN my_procedure(1, 'foo'); END;")</pre> |

| <code>database</code> | A database.                                                                                                                                                                                                                                                                                                                                                                                                         |                       |                         |                     |                                            |
| <code>count</code>    | An integer.                                                                                                                                                                                                                                                                                                                                                                                                         |                       |                         |                     |                                            |
| Description           | <p>The function <code>find-database</code>, given a string <code>database</code>, searches amongst the connected databases for one matching the name <code>database</code>.</p> <p>If there is exactly one such database, it is returned and the second return value <code>count</code> is 1. If more than one databases match and <code>errorp</code> is <code>nil</code>, then the most recently connected of</p> |                       |                         |                     |                                            |

the matching databases is returned and *count* is the number of matches. If no matching database is found and *errorp* is *nil*, then *nil* is returned. If none, or more than one, matching databases are found and *errorp* is true, then an error is signalled.

If the argument *database* is a database, it is simply returned.

## **initialize-database-type** *Function*

Summary      Initializes a database type.

Package      `sql`

Signature      `initialize-database-type &key database-type => type`

Arguments      *database-type*      A database type.

Values      *type*      A database type.

Description      The function `initialize-database-type` initializes a database type by loading code and appropriate database libraries according to the value of *database-type*. If `*default-database-type*` is not initialized, this function initializes it. It adds *database-type* to the list of initialized types. The initialized database type is returned.

Example      The following example shows how to use `initialize-database-type` to initialize the `:odbc` database type.

```
(require "odbc")
(in-package sql)
(setf *default-database-type* :odbc)
(initialize-database-type)
(print *initialized-database-types*)
```

The ODBC database type is now initialized, and connections can be made to ODBC databases.

## \*initialized-database-types\*

*Variable*

Summary A list of initialized database types.

Package `sql`

Initial Value `nil`

Description The variable `*initialized-database-types*` contains a list of database types that have been initialized by calls to `initialize-database-type`.

See also `initialize-database-type`

## insert-records

*Function*

Summary Inserts a set of values into a table.

Package `sql`

Signature `insert-records &key into attributes values av-pairs query database`

Arguments `into` A database table.

*This chapter applies to the Enterprise Edition only*

|             | <i>query</i>      | A query expression, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|             | <i>database</i>   | A database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Values      |                   | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description |                   | <p>The function <code>insert-records</code> inserts records into the table <i>into</i>.</p> <p>The records created contain <i>values</i> for <i>attributes</i> (or <i>av-pairs</i>). The argument <i>values</i> is a list of values. If <i>attributes</i> is supplied then <i>values</i> must be a corresponding list of values for each of the listed attribute names.</p> <p>If <i>av-pairs</i> is non-nil, then both <i>attributes</i> and <i>values</i> must be <code>nil</code>.</p> <p>If <i>query</i> is non-nil, then neither <i>values</i> nor <i>av-pairs</i> should be. <i>query</i> should be a query expression, and the attribute names in it must also exist in the table <i>into</i>.</p> <p>The default value of <i>database</i> is <code>*default-database*</code>.</p> |
| Example     |                   | <p>In the first example, the Lisp expression</p> <pre>(insert-records :into [person]   :values '("abc" "Joe" "Bloggs" 10000 3000 nil             "plumber"))</pre> <p>is equivalent to the following SQL:</p> <pre>INSERT INTO PERSON   VALUES ('abc','Joe',           'Bloggs',10000,3000,NULL,'plumber')</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

In the second example, the LispWorks expression

```
(insert-records :into [person]
 :attributes '(person_id income surname occupation)
 :values '("aaa" 10 "jim" "plumb"))
```

is equivalent to the following SQL:

```
INSERT INTO PERSON
 (PERSON_ID, INCOME, SURNAME, OCCUPATION)
 VALUES ('aaa', 10, 'jim', 'plumb')
```

The following example demonstrates how to use `:av-pairs`.

```
(insert-records :into [person] :av-pairs
 '((person_id "bbb") (surname "Jones")))
```

| Arguments   | <code>instance</code>                                                                                                                                                                                                                                                                                                                                                     | An instance of a View Class. |
| Values      | None.                                                                                                                                                                                                                                                                                                                                                                     |                              |
| Description | <p>The function <code>instance-refreshed</code> is called inside <code>select</code> when its <code>refresh</code> argument is true and the instance <code>instance</code> has just been updated.</p> <p>The supplied method on <code>standard-db-object</code> does nothing. If your application needs to take action when a View Class instance has been updated by</p> |                              |

```
(select ... :refresh t)
```

then add an `instance-refresh` method specializing on your subclass of `standard-db-object`.

| Description                 | <p>The function <b>list-attribute-types</b> returns type information for the attributes in the table given by <i>table</i>. <i>database</i> has a default value of <b>*default-database*</b>.</p> <p>If <i>owner</i> is <code>nil</code>, only user-owned attributes are considered. This is the default.</p> <p>If <i>owner</i> is <code>:all</code>, all attributes are considered.</p> <p>If <i>owner</i> is a string, this denotes a username and only attributes owned by <i>owner</i> are considered.</p> <p><i>result</i> is a list in which each element is a list (<i>attribute datatype precision scale nullable</i>). <i>attribute</i> is a string denoting the attribute name. <i>datatype</i> is the vendor-specific type as described in <b>attribute-type</b>. <i>nullable</i> is 1 if the attribute accepts the value NULL, and 0 otherwise.</p> |              |          |                 |             |              |                                                   |
| Example                     | To print the type of every attribute in the database, do                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |              |          |                 |             |              |                                                   |

|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | Returns a list of attributes from a table in a database.                                                                                                                                                                                                                                                                                                                                                                                                                |  |
| Package     | <b>sql</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  |
| Signature   | <b>list-attributes</b> <i>table</i> & <b>key</b> <i>database owner</i> => <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                 |  |
| Arguments   | <i>table</i> A table in the database.<br><i>database</i> A database.<br><i>owner</i> <b>nil</b> , <b>:all</b> or a string.                                                                                                                                                                                                                                                                                                                                              |  |
| Values      | <i>result</i> A list of attributes.                                                                                                                                                                                                                                                                                                                                                                                                                                     |  |
| Description | <p>The function <b>list-attributes</b> returns a list of attributes from <i>table</i> in <i>database</i>, which has a default value of <b>*default-database*</b>.</p> <p>If <i>owner</i> is <b>nil</b>, only user-owned attributes are considered. This is the default.</p> <p>If <i>owner</i> is <b>:all</b>, all attributes are considered.</p> <p>If <i>owner</i> is a string, this denotes a username and only attributes owned by <i>owner</i> are considered.</p> |  |

## **list-classes** *Function*

Summary     Returns a list of View Classes connected to a given database.

Package     **sql**

Signature    **list-classes &key database root-class test => result-list**

Arguments    **database**       A database.  
                **root-class**      A class.  
                **test**            A test function.

Values        **result-list**     A list of class objects.

Description    The function **list-classes** collects all the classes below **root-class** (which defaults to **standard-db-object**) that are connected to the given database specified by **database**, and which satisfy the **test** function. The default for the **test** argument is **cl:identity**.  
  
By default, **list-classes** returns a list of all the classes connected to the default database, **\*default-database\***.

## **list-sql-streams** *Function*

Summary     Returns the broadcast list of streams recording SQL commands or results traffic.

Package     **sql**

Signature    **list-sql-streams &key type database => streams**

|             |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments   | <i>type</i>     | A keyword.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|             | <i>database</i> | A database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Values      | <i>streams</i>  | A list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description |                 | <p>The function <code>list-sql-streams</code> returns the broadcast list of streams recording SQL commands or results traffic.</p> <p>Each element of <i>streams</i> is a stream or the symbol <code>t</code>, denoting <code>*standard-output*</code>.</p> <p>The keyword <i>type</i> is one of <code>:commands</code> or <code>:results</code>, and determines whether to return a list of streams for SQL commands or results traffic.</p> <p>The default value of <i>type</i> is <code>:commands</code>. The default value for <i>database</i> is the value of <code>*default-database*</code>.</p> |

| Accessors    | <code>lob-stream-lob-locator</code>                                                                                                                                                                                                                                                |
| Description  | The class <code>lob-stream</code> implements LOB streams in the Oracle LOB interface.<br><br>A <code>lob-stream</code> for input can be returned from <code>select</code> or <code>query</code> by specifying <code>:input-stream</code> as the type to return for the LOB column. |

A **lob-stream** for output can be returned from **select** or **query** by specifying **:output-stream** as the type to return for the LOB column.

A **lob-stream** can be attached to an existing LOB locator by creating the stream explicitly.

**direction** specifies whether the stream is for input or output. The default value of **direction** is **:input**.

By default, if the stream is closed the LOB locator is freed, unless **free-lab-locator-on-close** is passed as **nil**. The default value of **free-lab-locator-on-close** is **t**.

**Example** This creates an input stream connected to the LOB locator **lob-locator**.

```
(make-instance 'lob-stream :lob-locator lob-locator)
```

## locally-disable-sql-reader-syntax *Function*

**Summary** Turns off square bracket syntax and does not change syntax state.

**Package** **sql**

**Signature** **locally-disable-sql-reader-syntax =>**

**Arguments** None.

**Values** None.

**Description** The function **locally-disable-sql-reader-syntax** turns off square bracket syntax and does not change syntax state. This ensures that **restore-sql-reader-syntax-state** restores the current enable/disable state.

*This chapter applies to the Enterprise Edition only*

|         |                                                                                                                               |
|---------|-------------------------------------------------------------------------------------------------------------------------------|
| Example | The intended use of <code>locally-disable-sql-reader-syntax</code> is in a file:                                              |
|         | <pre>#.(locally-disable-sql-reader-syntax) &lt;Lisp code not using [...] syntax&gt; #.(restore-sql-reader-syntax-state)</pre> |

## **locally-enable-sql-reader-syntax** *Function*

Summary      Turns on square bracket syntax and does not change syntax state.

Package      `sql`

Signature      `locally-enable-sql-reader-syntax`

Arguments      None.

Values      None.

Description      The function `locally-enable-sql-reader-syntax` turns on square bracket syntax and does not change the syntax state. This ensures that `restore-sql-reader-syntax-state` restores the current enable/disable state.

Example      The intended use of `locally-enable-sql-reader-syntax` is in a file:

```
#.(locally-enable-sql-reader-syntax)
<code using [...] syntax>
#.(restore-sql-reader-syntax-state)
```

| Description | <p>The Common Lisp <b>loop</b> macro has been extended with a clause for iterating over query results. This extension is available only when Common SQL has been loaded. For a full description of the rest of the Common Lisp <b>loop</b> facility, including the possible return values, see the ANSI Common Lisp specification.</p> <p>Each iteration of the loop assigns the next record of the table to the variable <b>var</b>. The record is represented in Lisp as a list. Destructuring can be used in <b>var</b> to bind variables to specific</p> |  |

attributes of the records resulting from *query-expression*. In conjunction with the panoply of existing clauses available from the `loop` macro, the new iteration clause provides an integrated report generation facility.

The additional loop keywords `not-inside-transaction` and `get-all` may be useful when fetching many records through a connection with `database-type :mysql`. See the section “Special considerations for iteration functions and macros” on page 260 for details.

|         |                                                                                                                                                                                                                                                                                                                                                            |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example | This extended <code>loop</code> example performs the following on each record returned as a result of a query: bind <code>name</code> to the query result, find the salary (if any) from an associated hash-table, increment a count for salaries greater than 20000, accumulate the salary, and print the details. Finally, it prints the average salary. |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
(loop
 for (name) being each record in
 [select [ename] :from [emp]]
 as salary = (gethash name *salary-table*)
 initially (format t "~&~20A~10D" 'name 'salary)
 when (and salary (> salary 20000))
 count salary into salaries
 and sum salary into total
 and do (format t "~&~20A~10D" name salary)
 else
 do (format t "~&~20A~10A" name "N/A")
 finally
 (format t "~2&Av Salary: ~10D" (/ total salaries)))
```

|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Returns the results of mapping a function across a SQL query statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Package     | <code>sql</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Signature   | <code>map-query output-type-spec function query-exp &amp;key database not-inside-transaction get-all =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Arguments   | <p><i>output-type-spec</i> The output type specification.</p> <p><i>result-type</i> The result sequence type.</p> <p><i>function</i> A function.</p> <p><i>query-exp</i> A SQL query or a prepared-statement containing a query.</p> <p><i>database</i> A database.</p> <p><i>not-inside-transaction</i> A generalized boolean.</p> <p><i>get-all</i> A generalized boolean.</p>                                                                                                                                                                                                                                                                                                         |
| Values      | <p><i>result</i> A sequence of type <i>output-type-spec</i> containing the results of the map function.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Description | <p>The function <code>map-query</code> returns the result of mapping <i>function</i> across the results of <i>query-exp</i>. The <i>output-type-spec</i> argument specifies the type of the result sequence as per the Common Lisp <code>map</code> function.</p> <p>The default value of <i>database</i> is <code>*default-database*</code>.</p> <p><i>not-inside-transaction</i> and <i>get-all</i> may be useful when fetching many records through a connection with <i>database-type</i> <code>:mysql</code>. Both of these arguments have default value <code>nil</code>. See the section “Special considerations for iteration functions and macros” on page 260 for details.</p> |

*This chapter applies to the Enterprise Edition only*

Example      This example binds `name` to each name in the employee table and prints it.

```
(map-query
 nil
 #'(lambda (name) (print name))
 [select [ename] :from [emp] :flatp t])
```

## \*mysql-library-directories\*

*Variable*

Package      `sql`

Initial Value    `nil`

Description     The variable `*mysql-library-directories*` helps Lisp-Works for Windows to locate the MySQL library for use with `database-type :mysql`.

It specifies a directory or a list of directories in which to search for the MySQL library. If the value is a directory pathname specifier then it is passed to `directory`. If the value is a list of directory pathname specifiers then each item is passed to `directory`. The collected results are the list of directories to search in.

Notes        The default value `nil` causes the system to use `*mysql-library-sub-directories*` to construct the search path. With the default installation of MySQL this copes better with 64-bit/32-bit mixing on the same machine. When `*mysql-`

`*library-directories*` is non-nil, it overrides `*mysql-library-sub-directories*`.

Compatibility note In LispWorks 6.0 `*mysql-library-directories*` has initial value "C:\\Program Files\\MySQL\\MySQL\*\\bin".

In LispWorks 6.1 and later, `*mysql-library-directories*` has initial value nil so the search path is constructed using `*mysql-library-sub-directories*`.

See also `*mysql-library-path*`  
`*mysql-library-sub-directories*`

## **`*mysql-library-path*`** *Variable*

Package `sql`

Initial Value On Microsoft Windows:

`"libmysql.dll"`

On other platforms with pthreads:

`"-lmysqlclient_r"`

On other platforms without pthreads:

`"-lmysqlclient"`

Description The variable `*mysql-library-path*` helps the system to locate the MySQL library for use with *database-type* :`mysql`. It specifies the library name, and can also be set to a full path. If it is not a name, the system searches the standard library locations.

You can override the value of `*mysql-library-path*` by setting the environment variable `LW_MYSQL_LIBRARY`.

| Package                                | <code>sql</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                 |
| Initial Value                          | <code>"MySQL\\MySQL*\\bin"</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                 |
| Description                            | The variable <code>*mysql-library-sub-directories*</code> helps LispWorks for Windows to locate the MySQL library for use with <code>database-type :mysql</code> .<br><br>It specifies a directory in which to search for the MySQL library, as a sub-directory of the appropriate Program Files directory. On a 32-bit machine that normally means <code>C:\\Program Files\\</code> , while on a 64-bit machine it normally means <code>C:\\Program Files\\</code> for 64-bit programs and <code>C:\\Program Files (x86)\\</code> for 32-bit programs. |                 |
|                                        | The value must be a pathname designator. It is merged with the Program Files directory yielding a path (for example <code>"C:\\Program Files\\MySQL\\MySQL*\\bin"</code> ) which is then passed to <code>directory</code> . The result is a list of directories that are used to search for the MySQL library.                                                                                                                                                                                                                                          |                 |
|                                        | The default value matches the default MySQL installation.<br><br>If <code>*mysql-library-directories*</code> is non-nil, it overrides <code>*mysql-library-sub-directories*</code> .                                                                                                                                                                                                                                                                                                                                                                    |                 |
|                                        | Note that this default will match any MySQL release, so if you need to be sure to match a specific MySQL release, you need to change the value of <code>*mysql-library-sub-directories*</code> such that it matches only that particular release.                                                                                                                                                                                                                                                                                                       |                 |
| See also                               | <code>*mysql-library-directories*</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                 |

| Package     | <code>sql</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Signature   | <code>ora-lob-append src-lob-locator dest-lob-locator &amp;key errorp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Arguments   | <p><i>src-lob-locator</i> A LOB locator.</p> <p><i>dest-lob-locator</i> A LOB locator.</p> <p><i>errorp</i> A generalized boolean.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description | <p>The function <code>ora-lob-append</code> appends the contents of the LOB pointed to by <i>src-lob-locator</i> to the end of LOB pointed by <i>dest-lob-locator</i>. The source and destination LOBs must be of the same internal LOB type, that is, either both BLOB or both CLOB/NCLOB.</p> <p>If an error occurs and <i>errorp</i> is true, an error is signaled. If <i>errorp</i> is false, the function returns an object of type <code>sql-database-error</code>. The default value of <i>errorp</i> is <code>nil</code>.</p> <p><code>ora-lob-append</code> is applicable to internal LOBs only.</p> |
| Notes       | <ol style="list-style-type: none"> <li>1. <code>ora-lob-append</code> is a direct call OCILobAppend.</li> <li>2. <code>ora-lob-append</code> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.</li> </ol>                                                                                                                                                                                                                                                                                                                        |

|           | <i>Function</i>                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------|
| Summary   | Assigns a LOB to another LOB locator.                                                           |
| Package   | <code>sql</code>                                                                                |
| Signature | <code>ora-lob-assign src-lob-locator &amp;key dest-lob-locator errorp =&gt; lob--locator</code> |
| Arguments | <p><i>src-lob-locator</i> A LOB locator.</p> <p><i>dest-lob-locator</i> A LOB locator.</p>      |

|             | <i>errorp</i>      | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Values      | <i>lob-locator</i> | A LOB locator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description |                    | <p>The function <code>ora-lob-assign</code> assigns the underlying LOB for <i>src-lob-locator</i> to another LOB locator.</p> <p>If <i>dest-lob-locator</i> is <code>nil</code> then a new LOB locator is created and returned. Otherwise <i>dest-lob-locator</i> should be an existing LOB locator which is modified and returned. The default value of <i>dest-lob-locator</i> is <code>nil</code>.</p> <p>If an error occurs and <i>errorp</i> is true, an error is signaled. If <i>errorp</i> is false, the function returns an object of type <code>sql-database-error</code>. The default value of <i>errorp</i> is <code>nil</code>.</p> |
| Notes       |                    | <ol style="list-style-type: none"><li>1. <code>ora-lob-assign</code> is a direct call to <code>OCILobAssign</code>.</li><li>2. <code>ora-lob-assign</code> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.</li></ol>                                                                                                                                                                                                                                                                                                                                             |

| ora-lob-char-set-form |                    | <i>Function</i>                                                                                                      |
|-----------------------|--------------------|----------------------------------------------------------------------------------------------------------------------|
| Summary               |                    | Returns the character set form of a LOB.                                                                             |
| Package               |                    | <code>sql</code>                                                                                                     |
| Signature             |                    | <code>ora-lob-char-set-form lob-locator &amp;key errorp =&gt; charset</code>                                         |
| Arguments             | <i>lob-locator</i> | A LOB locator.                                                                                                       |
|                       | <i>errorp</i>      | A generalized boolean.                                                                                               |
| Values                | <i>charset</i>     | A non-negative integer.                                                                                              |
| Description           |                    | The function <code>ora-lob-char-set-form</code> returns the char set form of the LOB underlying <i>lob-locator</i> . |

`charset` is 0 for a binary LOB (BLOB or BFILE),  
 SQLCS\_IMPLICIT (1) for a character LOB (CFILE or CLOB)  
 and SQLCS\_NCHAR (2) for a NCLOB.

If an error occurs and `errorp` is true, an error is signaled. If `errorp` is false, the function returns an object of type `sql-database-error`. The default value of `errorp` is `nil`.

**Notes**

1. This is a direct call to OCILobCharSetForm.
2. `ora-lob-char-set-form` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

| Description | <p>The function <code>ora-lob-copy</code> copies part of the LOB pointed to by <code>src-lob-locator</code> into the LOB pointed to by <code>dest-lob-locator</code>. The details of the operation are determined by <code>amount</code>, <code>src-offset</code> and <code>dest-offset</code>. These numbers are in characters for CLOB/NCLOB and bytes for BLOB, and the offsets start from 1. The part of the source LOB from offset <code>src-offset</code> of length <code>amount</code> is copied into the destination LOB at offset <code>dest-offset</code>. The default value of <code>dest-offset</code> is 1 and the default value of <code>src-offset</code> is 1.</p> <p>The destination LOB is extended if needed. If the <code>dest-offset</code> is beyond the end of the destination LOB, the gap between the end and <code>dest-offset</code> is erased, that is, filled with 0 for BLOBs or spaces for CLOBS.</p> <p>Both LOBs must be internal LOBs, and they must be of the same type, that is, either both BLOB or both CLOB/NCLOB.</p> <p><code>ora-lob-append</code> is applicable to internal LOBs only.</p> <p>If an error occurs and <code>errorp</code> is true, an error is signaled. If <code>errorp</code> is false, the function returns an object of type <code>sql-database-error</code>. The default value of <code>errorp</code> is <code>nil</code>.</p> |

## **ora-lob-create-empty**                                  *Function*

Summary      Creates an empty LOB.

Package      **sql**

Signature      **ora-lob-create-empty &key db type => lob-locator**

Arguments      *db*                          A database.

*type*                          A Lisp object.

Values      *lob-locator*                          A LOB locator.

Description      The function **ora-lob-create-empty** creates an empty LOB object and returns a LOB locator for it.

If *type* is :lob then **ora-lob-create-empty** creates a LOB of type BLOB/CLOB. If *type* is any other value, it creates a file LOB. The default value of *type* is :lob.

Empty LOBs can be put in the database by passing them to **insert-records** or **update-records**. However, the preferred approach is to use the Oracle SQL function EMPTY\_BLOB as described in the section "Inserting empty LOBs" on page 265.

The default value of *db* is the value of \*default-database\*.

Notes      **ora-lob-create-empty** is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

| Description              | The function <b>ora-lob-create-temporary</b> creates a temporary LOB.<br><br><i>db-or-lob-locator</i> specifies the database to associate the new LOB with. If it is a LOB locator the database from which the LOB locator came is used.<br><br>If an error occurs and <i>errorp</i> is true, an error is signaled. If <i>errorp</i> is false, the function returns an object of type <b>sql-database-error</b> . The default value of <i>errorp</i> is <b>nil</b> .<br><br><i>cache</i> specifies whether to use a cache or not. The default value of <i>cache</i> is <b>nil</b> .<br><br><i>session-duration</i> specifies the lifetime: if it is true then it uses OCI_DURATION_SESSION, otherwise it uses OCI_DURATION_CALL. The default value of <i>session-duration</i> is <b>t</b> . |                                                                                                                                      |

*This chapter applies to the Enterprise Edition only*

If *clob-p* is true then the new LOB is a CLOB, otherwise it is a BLOB. The default value of *clob-p* is *nil*.

The new temporary LOB locator is returned.

## ora-lob-element-type *Function*

Summary      Returns the Lisp element type corresponding to that of a LOB locator.

Package      `sql`

Signature      `ora-lob-element-type lob-locator => type`

Arguments      `lob-locator`      A LOB locator.

Values      `type`      A Lisp type descriptor.

Description      The function `ora-lob-element-type` returns the Lisp element type that best corresponds to the charset of the LOB locator `lob-locator`.

For BLOB and BFILE `type` is `(unsigned-byte 8)`. For CLOB, NCLOB and CFILE `type` is either `base-char` or `simple-char`, depending on the charset.

Notes      `ora-lob-element-type` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

## ora-lob-enable-buffering *Function*

Summary      Enables the buffering of the Oracle client.

*This chapter applies to the Enterprise Edition only*

| Description | The function <b>ora-lob-erase</b> erases part of the LOB pointed to by <i>lob-locator</i> . That is, it fills part of the LOB with 0 for BLOBs or spaces for CLOBs. | The operation starts from offset <i>offset</i> into the LOB and erases <i>amount</i> of data in the LOB, or to the end of the LOB. Note that the offset starts from 1, and that <i>offset</i> and <i>amount</i> are in characters for CLOBs and bytes for BLOB.<br><br>Erasing does not extend beyond the end of the LOB. The return value <i>erased</i> is the number of characters or bytes |

erased. *erased* will be smaller than *amount* if the sum of *offset* and *amount* is greater than the length of the LOB.

**ora-lob-erase** is applicable to internal LOBs only.

If an error occurs and *errorp* is true, an error is signaled. If *errorp* is false, the function returns an object of type **sql-database-error**. The default value of *errorp* is **nil**.

## **ora-lob-file-close-all** *Function*

Summary      Closes all the file LOBs.

Package      **sql**

Signature      **ora-lob-file-close-all &key db errorp**

Arguments      **db**                  A database.

**errorp**                A generalized boolean.

Description      The function **ora-lob-file-close-all** closes the files that are associated with all the file LOB locators that are opened through the database connection specified by *database*.

The default value of *db* is the value of **\*default-database\***.

If an error occurs and *errorp* is true, an error is signaled. If *errorp* is false, the function returns an object of type **sql-database-error**. The default value of *errorp* is **nil**.

Notes      1. This is a direct call to OCILobFileCloseAll.

2. **ora-lob-file-close-all** is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

See also      **ora-lob-file-close**

## **ora-lob-file-exists** *Function*

Summary      The predicate for whether a LOB file exists.

Package      **sql**

*This chapter applies to the Enterprise Edition only*

## `ora-lob-file-is-open`

*Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary     | The predicate for whether a LOB file is open.                                                                                                                                                                                                                                                                                                                                                                                   |  |
| Package     | <code>sql</code>                                                                                                                                                                                                                                                                                                                                                                                                                |  |
| Signature   | <code>ora-lob-file-is-open lob-locator &amp;key errorp =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                      |  |
| Arguments   | <code>lob-locator</code> A LOB locator.<br><code>errorp</code> A generalized boolean.                                                                                                                                                                                                                                                                                                                                           |  |
| Values      | <code>result</code> A boolean.                                                                                                                                                                                                                                                                                                                                                                                                  |  |
| Description | <p>The function <code>ora-lob-file-is-open</code> returns <code>t</code> if the file associated with the LOB is open. This function is applicable only to file LOBs (CFILE or BFILE).</p> <p>If an error occurs and <i>errorp</i> is true, an error is signaled. If <i>errorp</i> is false, the function returns an object of type <code>sql-database-error</code>. The default value of <i>errorp</i> is <code>nil</code>.</p> |  |
| Notes       | <ol style="list-style-type: none"> <li>1. This is a direct call to OCILobFileIsOpen.</li> </ol>                                                                                                                                                                                                                                                                                                                                 |  |

*This chapter applies to the Enterprise Edition only*

2. **ora-lob-file-is-open** is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

## **ora-lob-file-open** *Function*

|             |                                                                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Opens a file LOB.                                                                                                                                                                                                                                                                                                                 |

| Signature           | <b>ora-lob-free</b> <i>lob-locator</i>                                                                                                                                                                                             |                 |
| Arguments           | <i>lob-locator</i>                                                                                                                                                                                                                 | A LOB locator.  |
| Description         | The function <b>ora-lob-free</b> frees the LOB locator <i>lob-locator</i> . If <i>lob-locator</i> was retrieved inside an iteration macro or function (that is, one of <b>map-query</b> , <b>do-query</b> , <b>simple-do-query</b> |                 |

and loop), it is freed before the next record is fetched, or when terminating the iteration for the last record.

LOB locators which were retrieved by `select` or `query`, or were created by the user by `ora-lab-assign` or `ora-lab-create-empty` are freed automatically when the database connection is closed by a call to `disconnect`.

If you create many LOB locators without closing the connection, it is useful to free them by calling `ora-lab-free`, to free the resources that are associated with them.

Freeing a LOB locator does not affect the underlying LOB. In particular, after modifications to the LOB there is no `roll-back` even if there was not yet a `commit`.

**Notes** `ora-lab-free` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

## **ora-lob-get-buffer** *Function*

|             |                                                                                                                            |                                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| Summary     | Gets a buffer for efficient I/O with foreign functions.                                                                    |                                        |
| Package     | <b>sql</b>                                                                                                                 |                                        |
| Signature   | <b>ora-lob-get-buffer</b> <i>lob-locator &amp;key for-writing offset =&gt; amount/size, foreign-buffer, eof-or-error-p</i> |                                        |
| Arguments   | <i>lob-locator</i>                                                                                                         | A LOB locator.                         |
|             | <i>for-writing</i>                                                                                                         | A generalized boolean.                 |
|             | <i>offset</i>                                                                                                              | A non-negative integer or <b>nil</b> . |
| Values      | <i>amount/size</i>                                                                                                         | A non-negative integer.                |
|             | <i>foreign-buffer</i>                                                                                                      | A FLI pointer.                         |
|             | <i>eof-or-error-p</i>                                                                                                      | A boolean or an error object.          |
| Description | The function <b>ora-lob-get-buffer</b> gets a buffer for efficient I/O with foreign functions.                             |                                        |

If *for-writing* is `nil`, then `ora-lob-get-buffer` fills an internal buffer and returns three values: *amount/size* is how much it filled, *foreign-buffer* points to the actual buffer, and *eof-or-error-p* is the return value from the call to `ora-lob-read-foreign-buffer`. The offset *offset* is passed directly `ora-lob-read-foreign-buffer`.

If *for-writing* is true, then `ora-lob-get-buffer` returns two values: *amount/size* is the size of the foreign buffer and *foreign-buffer* points to the actual buffer, which then can be passed to `ora-lob-write-foreign-buffer`.

The default value of *for-writing* is `nil`.

The buffer that is used by `ora-lob-get-buffer` is always the same for the LOB locator, it is used by `ora-lob-read-buffer` and `ora-lob-write-buffer`, and is freed automatically when the LOB locator is freed. Thus until you finish with the buffer, you cannot use `ora-lob-read-buffer` or `ora-lob-write-buffer` or call `ora-lob-get-buffer` again or free the LOB locator.

#### Notes

`ora-lob-get-buffer` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

#### Example

This first example illustrates reading using the buffer obtained by `ora-lob-get-buffer`. You have a foreign function:

```
my_chunk_processor(char *data, int size)
```

with this FLI definition:

```
(fli:define-foreign-function my_chunk_processor
 ((data :pointer)
 (size :int)))
```

You can pass all the data from the LOB locator to this function. Assuming no other function reads from it, it will start from the beginning.

*This chapter applies to the Enterprise Edition only*

```
(loop
 (multiple-value-bind (amount buffer eof-or-error-p)
 (ora-lob-get-buffer lob)
 (when (zerop amount) (return))
 (my_chunk_processor buffer amount))
```

This second example illustrates writing with the buffer obtained by `ora-lob-get-buffer`. You have a foreign function that fills a buffer with data, and you want to write it to a LOB. First you should lock the record, and if required trim the LOB locator.

```
(multiple-value-bind (size buffer)
 (ora-lob-get-buffer lob-locator
 :for-writing t
 ;;= start at the beginning
 :offset 1)
 (loop (let ((amount (my-fill-buffer buffer size)))
 (when (zerop amount) (return))
 (ora-lob-write-foreign-buffer
 lob-locator nil
 amount buffer size))))
```

## ora-lob-get-chunk-size

*Function*

Summary      Returns the chunk size of a LOB.

Package      `sql`

Signature      `ora-lob-get-chunk-size lob-locator &key errorp => size`

Arguments      `lob-locator`      A LOB locator.

`errorp`      A generalized boolean.

Values      `size`      A non-negative integer.

|             |                                                                                                                                                                                                                                                                                                                                                                                                           |

| <i>lob-locator</i> | A LOB locator.                                                                                                                                                                                                                                                                                                                                                 |                    |                |               |                        |
| <i>errorp</i>      | A generalized boolean.                                                                                                                                                                                                                                                                                                                                         |                    |                |               |                        |
| Values             | <i>length</i> A non-negative integer.                                                                                                                                                                                                                                                                                                                          |                    |                |               |                        |
| Description        | <p>The function <code>ora-lob-get-length</code> returns the current length of the LOB underlying <i>lob-locator</i>.</p> <p>If an error occurs and <i>errorp</i> is true, an error is signaled. If <i>errorp</i> is false, the function returns an object of type <code>sql-database-error</code>. The default value of <i>errorp</i> is <code>nil</code>.</p> |                    |                |               |                        |
| Notes              | <ol style="list-style-type: none"> <li>1. This is a direct call to <code>OCILobGetLength</code>.</li> </ol>                                                                                                                                                                                                                                                    |                    |                |               |                        |

*This chapter applies to the Enterprise Edition only*

2. `ora-lob-get-length` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

## **ora-lob-internal-lob-p** *Function*

|             |                                                                                                                                                                           |                |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| Summary     | The predicate for internal LOBs.                                                                                                                                          |                |
| Package     | <code>sql</code>                                                                                                                                                          |                |
| Signature   | <code>ora-lob-internal-lob-p lob-locator =&gt; result</code>                                                                                                              |                |
| Arguments   | <i>lob-locator</i>                                                                                                                                                        | A LOB locator. |
| Values      | <i>result</i>                                                                                                                                                             | A boolean.     |
| Description | The function <code>ora-lob-internal-lob-p</code> returns <code>t</code> if <i>lob-locator</i> is internal (BLOB, CLOB, or NCLOB). Otherwise it returns <code>nil</code> . |                |
| Notes       | <code>ora-lob-internal-lob-p</code> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.        |                |

## **ora-lob-is-equal** *Function*

|           |                                                                      |                |
|-----------|----------------------------------------------------------------------|----------------|
| Summary   | The comparison function for LOB locators.                            |                |
| Package   | <code>sql</code>                                                     |                |
| Signature | <code>ora-lob-is-equal lob-locator1 lob-locator2 =&gt; result</code> |                |
| Arguments | <i>lob-locator1</i>                                                  | A LOB locator. |
|           | <i>lob-locator2</i>                                                  | A LOB locator. |

|             |                                                                                                                                                                                                                                                                       |            |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| Values      | <i>result</i>                                                                                                                                                                                                                                                         | A boolean. |
| Description | The function <code>ora-lob-is-equal</code> returns <code>t</code> if <i>lob-locator1</i> and <i>lob-locator2</i> point to the same LOB object.                                                                                                                        |            |
| Notes       | <ol style="list-style-type: none"> <li>1. This is a direct call to OCILobIsEqual.</li> <li>2. <code>ora-lob-is-equal</code> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.</li> </ol> |            |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <i>Function</i>    |                |               |                        |  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|----------------|---------------|------------------------|--|
| Summary            | The predicate for whether a LOB locator is opened.                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |                |               |                        |  |

| Description        | <p>The function <code>ora-lob-is-open</code> returns <code>t</code> if the LOB pointed to by <i>lob-locator</i> is opened (by <code>ora-lob-open</code>).</p> <p><code>ora-lob-is-open</code> is applicable to internal LOBs only.</p> <p>If an error occurs and <i>errorp</i> is true, an error is signaled. If <i>errorp</i> is false, the function returns an object of type <code>sql-database-error</code>. The default value of <i>errorp</i> is <code>nil</code>.</p> |                    |                |               |                        |  |
| Notes              | <ol style="list-style-type: none"> <li>1. This is a direct call to OCILobIsOpen.</li> <li>2. <code>ora-lob-is-open</code> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.</li> </ol>                                                                                                                                                                                                          |                    |                |               |                        |  |

| Package     | <code>sql</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Signature   | <code>ora-lob-load-from-file dest-lob-locator src-lob-file amount &amp;key src-offset dest-offset errorp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Arguments   | <p><code>dest-lob-locator</code> An internal LOB locator.</p> <p><code>src-lob-file</code> A file LOB locator.</p> <p><code>amount</code> A non-negative integer.</p> <p><code>src-offset</code> A non-negative integer.</p> <p><code>dest-offset</code> A non-negative integer.</p> <p><code>errorp</code> A generalized boolean.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description | <p>The function <code>ora-lob-load-from-file</code> loads the data from the <code>src-lob-file</code> into the destination LOB pointed to by <code>dest-lob-locator</code>.</p> <p>The source LOB must be a BFILE and the destination must be an internal LOB.</p> <p>The details of the operation are determined by <code>amount</code>, <code>src-offset</code> and <code>dest-offset</code>. <code>amount</code> and <code>dest-offset</code> are in characters for CLOB/NCLOB and are in bytes for BLOB. <code>src-offset</code> is in bytes. The offsets start from 1. The default value of <code>dest-offset</code> is 1 and the default value of <code>src-offset</code> is 1.</p> <p>No conversion is performed by <code>ora-lob-load-from-file</code>, so if the destination is a CLOB/NCLOB, the source must already be in the right format.</p> <p>If an error occurs and <code>errorp</code> is true, an error is signaled. If <code>errorp</code> is false, the function returns an object of type <code>sql-database-error</code>. The default value of <code>errorp</code> is <code>nil</code>.</p> |
| Notes       | <ol style="list-style-type: none"> <li>1. This is a direct call to OCILobLoadFromFile. The Oracle documentation is ambiguous on whether it is mandatory to open the source LOB before calling this function.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

*This chapter applies to the Enterprise Edition only*

2. `ora-lob-load-from-file` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

## **ora-lob-lob-locator** *Function*

|             |                                                                                                                                                                                                                                           |                    |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| Summary     | Returns a foreign pointer to the underlying LOB locator.                                                                                                                                                                                  |                    |
| Package     | <code>sql</code>                                                                                                                                                                                                                          |                    |
| Signature   | <code>ora-lob-lob-locator lob-locator =&gt; pointer</code>                                                                                                                                                                                |                    |
| Arguments   | <code>lob-locator</code>                                                                                                                                                                                                                  | A LOB locator.     |
| Values      | <code>pointer</code>                                                                                                                                                                                                                      | A foreign pointer. |
| Description | <p>The function <code>ora-lob-lob-locator</code> returns a foreign pointer to the OCI LOB locator underlying <code>lob-locator</code>.<br/><code>pointer</code> is of type <code>p-oci-lob-locator</code> or <code>p-oci-file</code>.</p> |                    |
| Notes       | <p><code>ora-lob-lob-locator</code> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.</p>                                                                    |                    |

## **ora-lob-locator-is-init** *Function*

|           |                                                                               |  |
|-----------|-------------------------------------------------------------------------------|--|
| Summary   | The predicate for whether a LOB is initialized.                               |  |
| Package   | <code>sql</code>                                                              |  |
| Signature | <code>ora-lob-locator-is-init lob-locator &amp;key errorp =&gt; result</code> |  |

|             |                    |                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments   | <i>lob-locator</i> | A LOB locator.                                                                                                                                                                                                                                                                                                                                                              |
|             | <i>errorp</i>      | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                      |
| Values      | <i>result</i>      | A boolean.                                                                                                                                                                                                                                                                                                                                                                  |
| Description |                    | <p>The function <code>ora-lob-locator-is-init</code> returns <code>t</code> if the LOB locator <i>lob-locator</i> is initialized.</p> <p>If an error occurs and <i>errorp</i> is true, an error is signaled. If <i>errorp</i> is false, the function returns an object of type <code>sql-database-error</code>. The default value of <i>errorp</i> is <code>nil</code>.</p> |

| Arguments           | <i>lob-locator</i> | A LOB locator.                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                     | <i>errorp</i>      | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                         |
| Description         |                    | <p>The function <code>ora-lob-open</code> opens the LOB pointed to by <i>lob-locator</i>, which can be an internal LOB or a file LOB.</p> <p>Opening the LOB creates a transaction, so any updates associated with modifying the LOB are delayed until the <code>ora-lob-close</code> call. This saves round-trips and avoids extra work on the server side. However it is not mandatory to use <code>ora-lob-open</code>.</p> |

*This chapter applies to the Enterprise Edition only*

Calls to `ora-lob-open` must be strictly paired to calls to `ora-lob-close`, and the latter must be called before a call to `commit`. It is also an error to call `ora-lob-open` on a server LOB object that is already open, even if it has been opened via a different LOB locator.

If an error occurs and `errorp` is true, an error is signaled. If `errorp` is false, the function returns an object of type `sql-database-error`. The default value of `errorp` is `nil`.

Notes

1. This is a direct call to `OCILobOpen`.
2. `ora-lob-open` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

## ora-lob-read-buffer

## *Function*

Summary      Reads from a LOB into a buffer.

Package      `sql`

Signature      `ora-lob-read-buffer lob-locator offset amount buffer &key  
buffer-offset csid => amount-read, eof-or-error-p`

Arguments      `lob-locator`      A LOB locator.

`offset`      A non-negative integer or `nil`.

`amount`      A non-negative integer.

`buffer`      A string, or a vector of element type  
`(unsigned-byte 8)`.

`buffer-offset`      A non-negative integer.

`csid`      A Character Set ID

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                               |

| Values      | <i>amount-read</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | A non-negative integer.       |
|             | <i>eof-or-error-p</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | A boolean or an error object. |
| Description | <p>The function <code>ora-lob-read-buffer</code> reads into <i>buffer</i> from the LOB pointed to by <i>lob-locator</i>.</p> <p><i>offset</i> specifies the offset to start reading from. It starts with 1, and specifies characters for CLOB/NCLOB/CFILE and bytes for BLOB/BFILE. If <i>offset</i> is <code>nil</code> then the offset after the end of the previous read operation is used (write operations are ignored). This is especially useful for reading linearly from the LOB.</p> <p><i>amount</i> is the amount to read, in characters for CLOB/NCLOB/CFILE and bytes for BLOB/BFILE.</p> <p>The element type of <i>buffer</i> should match the element type of the LOB locator (see <code>ora-lob-element-type</code>). For this comparison (<code>unsigned-byte 8</code>) and <code>base-char</code> are considered as the same.</p> <p>If the buffer <i>buffer</i> is not static, there is some additional overhead. For small amounts of data, this is probably insignificant.</p> <p><i>buffer-offset</i> specifies where to put the data. It is an offset in bytes from the beginning of the buffer. The default value of <i>buffer-offset</i> is 0.</p> <p><i>csid</i> specifies what Character Set ID the data in the target buffer should be. It defaults to the CSID of the LOB pointed to by <i>lob-locator</i>.</p> <p>The return value <i>amount-read</i> is the number of elements (characters or bytes) that were read.</p> <p>If the return value <i>eof-or-error-p</i> is <code>nil</code> then there is still more to read. If <i>eof-or-error-p</i> is <code>t</code> then it read to the end of the LOB. If an error occurred then <i>eof-or-error-p</i> is an error object.</p> |                               |
| Notes       | <ol style="list-style-type: none"> <li>1. This is a direct call to OCILobRead, without callback.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                               |

*This chapter applies to the Enterprise Edition only*

2. `ora-lob-read-buffer` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

|         |                                                                                                                                                                                                                            |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example | This example sequentially reads the LOB data into a string, starting from offset 10000. It calls a processing function on each chunk of data and then reads in the next chunk starting from where the previous read ended. |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
(let ((my-buffer (make-string 1000
 :element-type 'base-char))
 (offset 10000))
 (loop
 (let ((nread
 (ora-lob-read-buffer lob-locator
 offset
 1000
 my-buffer)))
 (when (zerop nread) ; end of the LOB
 (return))
 (my-processing-function my-buffer nread))
 (setq offset nil))) ; so next time it continues
 ; from where it finished
```

## **ora-lob-read-into-plain-file** *Function*

|         |                                           |
|---------|-------------------------------------------|
| Summary | Writes the contents of a LOB into a file. |
|---------|-------------------------------------------|

|         |                  |
|---------|------------------|
| Package | <code>sql</code> |
|---------|------------------|

|           |                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------|
| Signature | <code>ora-lob-read-into-plain-file lob-locator file-name &amp;key<br/>offset file-offset if-exists</code> |
|-----------|-----------------------------------------------------------------------------------------------------------|

|           |                          |                                               |
|-----------|--------------------------|-----------------------------------------------|
| Arguments | <code>lob-locator</code> | A LOB locator.                                |
|           | <code>file-name</code>   | A pathname designator.                        |
|           | <code>offset</code>      | A non-negative integer, or <code>nil</code> . |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                               |

| Description | <p>The function <code>ora-lob-read-into-plain-file</code> writes the contents of a LOB into a file.</p> <p><i>file-name</i> specifies the file to write, which should be a standard file. The file is always opened in a binary mode, so if the LOB is a CLOB, the file will be generated in the right format when reading it from the LOB.</p> <p><i>offset</i> is the offset into the LOB from where to start reading. It starts from 1, counts characters in a CLOB, and if it is <code>nil</code> then the operation starts from the end of the previous read operation. The default value of <i>offset</i> is <code>nil</code>.</p> <p><i>file-offset</i> specifies the offset into the file to start the operation from. If <i>file-offset</i> is <code>nil</code> then it starts writing at the start of the file. The default value of <i>file-offset</i> is <code>nil</code>.</p> <p><i>if-exists</i> is passed to <code>open</code> when opening the file, with the standard Common Lisp meaning. The default value of <i>if-exists</i> is <code>:error</code>.</p> |                                               |
| Notes       | <p><code>ora-lob-read-into-plain-file</code> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                               |

| Description | The function <code>ora-lob-svc-ctx-handle</code> returns a foreign pointer to the context handle of the LOB underlying <i>lob-locator</i> .                        |                                                        |
| Notes       | <code>ora-lob-svc-ctx-handle</code> is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information. |                                                        |

|             |                                                                                                                                                                    | <i>Function</i>         |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| Summary     | Trims an internal LOB.                                                                                                                                             |                         |
| Package     | <code>sql</code>                                                                                                                                                   |                         |
| Signature   | <code>ora-lob-trim lob-locator new-size &amp;key errorp</code>                                                                                                     |                         |
| Arguments   | <i>lob-locator</i>                                                                                                                                                 | A LOB locator.          |
|             | <i>new-size</i>                                                                                                                                                    | A non-negative integer. |
|             | <i>errorp</i>                                                                                                                                                      | A generalized boolean.  |
| Description | The function <code>ora-lob-trim</code> trims the LOB pointed to by <i>lob-locator</i> to a new size <i>new-size</i> , which must be smaller than its current size. |                         |

*This chapter applies to the Enterprise Edition only*

Note that *new-size* is in characters for CLOBs and bytes for BLOBs.

**ora-lob-trim** is applicable to internal LOBs only.

If an error occurs and *errorp* is true, an error is signaled. If *errorp* is false, the function returns an object of type **sql-database-error**. The default value of *errorp* is **nil**.

- Notes
1. This is a direct call to OCILobTrim.
  2. **ora-lob-trim** is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

| Arguments | <i>lob-locator</i>          | A LOB locator.                                                                                                                    |
|           | <i>offset</i>               | A non-negative integer or <b>nil</b> .                                                                                            |
|           | <i>amount</i>               | A non-negative integer.                                                                                                           |
|           | <i>buffer</i>               | A string, or a vector of element type ( <b>unsigned-byte 8</b> ).                                                                 |
|           | <i>buffer-offset</i>        | A non-negative integer.                                                                                                           |
|           | <i>csid</i>                 | A Character Set ID                                                                                                                |
| Values    | <i>amount-written</i>       | A non-negative integer.                                                                                                           |
|           | <i>eof-or-error-p</i>       | A boolean or an error object.                                                                                                     |

|             |                                                                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>ora-lob-write-buffer</code> writes to the LOB pointed to by <i>lob-locator</i> from <i>buffer</i>.</p>                                                                                                                                                                                                                                  |
|             | <p><i>offset</i> specifies the offset to start writing to. It starts with 1, and specifies characters for CLOB/NCLOB/CFILE and bytes for BLOB/BFILE. If <i>offset</i> is <code>nil</code> then the offset after the end of the previous write operation is used (read operations are ignored). This is especially useful for writing linearly to the LOB.</p> |
|             | <p><i>amount</i> is the amount to write, in characters for CLOB/NCLOB/CFILE and bytes for BLOB/BFILE.</p>                                                                                                                                                                                                                                                     |
|             | <p>The element type of <i>buffer</i> should match the element type of the LOB locator (see <code>ora-lob-element-type</code>). For this comparison (<code>unsigned-byte 8</code>) and <code>base-char</code> are considered as the same.</p>                                                                                                                  |
|             | <p>If the buffer <i>buffer</i> is not static, there is some additional overhead. For small amounts of data, this is probably insignificant.</p>                                                                                                                                                                                                               |
|             | <p><i>buffer-offset</i> specifies where in the buffer to start writing data from. It is an offset in bytes from the beginning of the buffer. The default value of <i>buffer-offset</i> is 0.</p>                                                                                                                                                              |
|             | <p><i>csid</i> specifies what Character Set ID the data in the source buffer should be. It defaults to the CSID of the LOB pointed to by <i>lob-locator</i>.</p>                                                                                                                                                                                              |
|             | <p>The return value <i>amount-written</i> is the number of elements (characters or bytes) that were written</p>                                                                                                                                                                                                                                               |
|             | <p>The LOB is extended as required.</p>                                                                                                                                                                                                                                                                                                                       |
|             | <p>If the return value <i>eof-or-error-p</i> is <code>nil</code> then there is still more to write. If <i>eof-or-error-p</i> is <code>t</code> then it wrote to the end of the LOB. If an error occurred then <i>eof-or-error-p</i> is an error object.</p>                                                                                                   |
| Notes       | <ol style="list-style-type: none"> <li>1. The record from which the LOB came must be locked. See the section “Locking” on page 266.</li> </ol>                                                                                                                                                                                                                |

*This chapter applies to the Enterprise Edition only*

2. `ora-lob-write-buffer` is a direct call to OCILobWrite, without callback.
3. `ora-lob-write-buffer` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

|             | <b>Function</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Writes the contents of a file into a LOB.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Package     | <code>sql</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Signature   | <code>ora-lob-write-from-plain-file lob-locator file-name &amp;key offset file-offset if-does-not-exist</code>                                                                                                                                                                                                                                                                                                                                                                                  |
| Arguments   | <p><i>lob-locator</i>      A LOB locator.</p> <p><i>file-name</i>      A pathname designator.</p> <p><i>offset</i>      A non-negative integer, or <code>nil</code>.</p> <p><i>file-offset</i>      A non-negative integer, or <code>nil</code>.</p> <p><i>if-does-not-exist</i>      A keyword or <code>nil</code>.</p>                                                                                                                                                                        |
| Description | <p>The function <code>ora-lob-write-from-plain-file</code> writes the contents of a file into a LOB.</p> <p><i>file-name</i> specifies the file to read, which should be a standard file. The file is always opened in a binary mode, so if the LOB is a CLOB, the file must be in the right format when writing it into the LOB.</p> <p><i>offset</i> is the offset into the LOB from where to start writing. It starts from 1, counts characters in a CLOB, and if it is <code>nil</code></p> |

then the operation starts from the end of the previous write operation. The default value of *offset* is `nil`.

*file-offset* specifies the offset into the file to start the operation from. If *file-offset* is `nil` then it starts reading at the start of the file. The default value of *file-offset* is `nil`.

*if-does-not-exist* is passed to `open` when opening the file, with the standard Common Lisp meaning. The default value of *if-does-not-exist* is `:error`.

Notes      `ora-lob-write-from-plain-file` is available only when the "oracle" module is loaded. See the section "Oracle LOB interface" on page 264 for more information.

**p-oci-lob-locator** *FLI type descriptor*

Summary A foreign type representing objects in the Oracle interface.

Package `sql`

Description See “Interactions with foreign calls” on page 268 for details.

**p-oci-lob-or-file** *FLI type descriptor*

Summary A foreign type representing objects in the Oracle interface.

Package `sql`

Description See “Interactions with foreign calls” on page 268 for details.

**p-oci-svc-ctx** *FLI type descriptor*

Summary A foreign type representing objects in the Oracle interface.

Package `sql`

Description See “Interactions with foreign calls” on page 268 for details.

**prepare-statement** *Function*

Summary Returns a prepared-statement object for a sql-exp in a database.

Package `sql`

Signature `prepare-statement sql-exp &key database variable-types count flatp result-types => prepared-statement`

| Description | <p>The function <code>prepare-statement</code> returns a prepared-statement object for the SQL statement <i>sql-exp</i> in the database <i>database</i>. <i>sql-exp</i> can contain bind-variables in the form <code>:n</code> where <i>n</i> is a positive integer.</p> <p>If <i>database</i> is supplied, then the prepared-statement is associated with the database. Otherwise <code>set-prepared-statement-variables</code> will do the association even if it is called without a database.</p> <p>If <i>variable-types</i> is supplied, then it should be a list containing a keyword element for each bind-variable in <i>sql-exp</i>. It has an effect in two cases:</p> <ul style="list-style-type: none"><li>• <code>:string</code> forces the variable to be passed to the database as a string. That may be useful if you have numeric values in Lisp which are stored as strings in the database.</li><li>• <code>:date</code> cause an integer to be interpreted as a universal-time and be converted properly to an Oracle date.</li></ul> <p>If <i>variable-types</i> is not supplied, then the types will be chosen dynamically from the values passed to <code>set-prepared-statement-variables</code>.</p> <p>If <i>count</i> is supplied, then it should equal the maximum number of bind-variables in the <i>sql-exp</i>. If <i>count</i> is not supplied, then it is calculated from <i>sql-exp</i>.</p> |                                              |

*flatp* and *result-types* are interpreted the same as in `select`.

The result of `prepare-statement` is a prepared-statement. This can be used by calling `set-prepared-statement-variables` to actually bind the variable, and then use one of the querying or executing interfaces that take a SQL expression argument: `execute-command`, `query`, `do-query`, `simple-do-query`, `map-query` and the `loop for...being each record` construct.

A prepared-statement that is associated with a database should be destroyed (by `destroy-prepared-statement`) before the database is closed, otherwise it may leak memory.

Notes *sql-exp* can be any valid SQL expression, not only a query.

Examples Create a prepared-statement for a SQL expression:

```
(setq ps
 (sql:prepare-statement
 "insert into TABLETWO values(:1, :2)"))
```

Then insert records into TABLETWO (which has two columns) by repeatedly doing:

```
(sql:set-prepared-statement-variables
 ps
 (list value1 value2))

(sql:execute-command ps))
```

| Values             | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                  |                         |               |                    |                |                    |              |         |               |                   |                 |             |
| Description        | <p>The function <code>print-query</code> takes a symbolic SQL query expression and formatting information and prints onto <i>stream</i> a table containing the results of the query.</p> <p>A list of strings to use as column headings is given by <i>titles</i>, which has a default value of <code>nil</code>.</p> <p>The <i>formats</i> argument is a list of format strings used to print each attribute, and has a default value of <code>t</code>, which means that <code>~A</code> or <code>~VA</code> are used if sizes are provided or computed.</p> <p>The field sizes are given by <i>sizes</i>. It has a default value of <code>t</code>, which specifies that minimum sizes are computed.</p> <p>The output stream is given by <i>stream</i>, which has a default value of <code>t</code>. This specifies that <code>*standard-output*</code> is used.</p> |                  |                         |               |                    |                |                    |              |         |               |                   |                 |             |
| Examples           | The following call prints out two even columns of names and salaries:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                  |                         |               |                    |                |                    |              |         |               |                   |                 |             |

```
(print-query [select [surname] [income] :from [person]
 :titles '("NAME" "SALARY")])

| Summary             | Queries a database and returns a list of values.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                    |                                                                   |                    |                    |                     |                    |              |            |

| <i>result-list</i>  | A list of values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                    |                                                                   |                    |                    |                     |                    |              |            |
| <i>field-names</i>  | A list of strings.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                    |                                                                   |                    |                    |                     |                    |              |            |
| Description         | <p>The function <code>query</code> is the basic SQL query function. It queries the database specified by <i>database</i> with a SQL query statement given by <i>sql-exp</i>.</p> <p>The argument <i>database</i> defaults to <code>*default-database*</code>. <i>result-types</i> is a list of symbols such as <code>:string</code> and <code>:integer</code>, one for each field in the query, which are used to specify the types to return.</p> <p><i>flatp</i> is used as in <code>select</code>.</p> |                    |                                                                   |                    |                    |                     |                    |              |            |

*This chapter applies to the Enterprise Edition only*

*result-list* is a list of values as per `select`, and *field-names* is a list of field names selected in *sql-exp*.

**Example** The following two queries, on a table whose second column contains dates that we want to return as strings, are equivalent:

```
(sql:query "select * from some_table"
 :result-types '(nil :string))

(sql:query [select [*]
 :from [some_table]
 :result-types '(nil :string)])
```

| Summary          |                       | Reconnects a database to its underlying RDBMS.                     |
| Package          |                       | <code>sql</code>                                                   |
| Signature        |                       | <code>reconnect &amp;key database error force =&gt; success</code> |
| Arguments        | <code>database</code> | The database to be reconnected.                                    |
|                  | <code>error</code>    | A boolean.                                                         |
|                  | <code>force</code>    | A boolean.                                                         |
| Values           | <code>success</code>  | A boolean.                                                         |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The function <code>reconnect</code> reconnects <i>database</i> to its underlying RDBMS. If successful, <i>success</i> is <code>t</code> and the variable <code>*default-database*</code> is set to the newly reconnected database.</p> <p>The default value for <i>database</i> is <code>*default-database*</code>. If <i>database</i> is a database object, then it is used directly. Otherwise, the list of connected databases is searched to find one with <i>database</i> as its connection specifications (see <code>connect</code>). If no such database is found, then if <i>error</i> and <i>database</i> are both non-nil an error is signaled, otherwise <code>reconnect</code> returns <code>nil</code>.</p> <p><i>force</i> controls whether an error should be signaled if the existing database connection cannot be closed. When non-nil (this is the default value) the connection is closed without error checking. When <i>force</i> is <code>nil</code>, an error is signaled if the database connection has been lost.</p> |
| Notes       | <i>force</i> non-nil might result in a memory leak if the database driver fails to release its memory (some drivers do not allow the connection to be closed if the underlying RDBMS is not responding).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Description | The function <code>restore-sql-reader-syntax-state</code> sets the enable/disable state of the square bracket syntax to reflect the last call to either <code>enable-sql-reader-syntax</code> or <code>disable-sql-reader-syntax</code> . The default state of the square bracket syntax is disabled. |

| Arguments       | <code>database</code> A database.                                                                                                                                                                                                                         |
| Values          | <code>nil</code>                                                                                                                                                                                                                                          |
| Description     | The function <code>rollback</code> rolls back changes made in <code>database</code> since the last commit, that is, changes made since the last commit are not recorded. The argument <code>database</code> defaults to <code>*default-database*</code> . |
| See also        | <code>commit</code><br><code>with-transaction</code>                                                                                                                                                                                                      |

|             | <b>select</b>                                                                                                                                                                                                                                                                                                                | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                            |

| Summary     | Selects data from a database given a number of specified constraints.                                                                                                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                            |
| Package     | <code>sql</code>                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                            |

| Description | The function <b>select</b> selects data from <i>database</i> , which has a default value of <code>*default-database*</code> , given the constraints specified by the rest of the arguments. It returns a list of                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                            |

objects as specified by *selections*. By default, the objects will each be represented as lists of attribute values.

The argument *selections* consists either of database identifiers, type-modified database identifiers or literal strings.

A type-modified database identifier is an expression such as `[foo :string]` which means that the values in column `foo` are returned as Lisp strings. This syntax can be used to force values in time/date fields to be returned as strings (see below for an example). It can also be used to affect the value returned from MySQL, using the keywords mentioned in the section “Using MySQL” on page 258. It can also be used to return `lob-stream` objects for queries on Oracle LOB columns, using an expression like `[foo :input-stream]` or `[foo :output-stream]`

*result-types* is used when *selections* is `*` or `[*]`. It should be a list of symbols such as `:string` and `:integer`, one for each field in the table being selected in order to specify the types to return. Note that, for specific selections, the result type can be specified by using a type-modified identifier as described above. However, you cannot use *result-types* to modify the type returned from a time/date field.

The *flatp* argument, which has a default value of `nil`, specifies if full bracketed results should be returned for each matched entry. If *flatp* is `nil`, the results are returned as a list of lists. If *flatp* is `t`, the results are returned as elements of a list, only if there is only one result per row. See the examples section for an example of the use of *flatp*.

The arguments *all*, *set-operation*, *distinct*, *from*, *where*, *group-by*, *having* and *order-by* have the same function as the equivalent SQL expression.

*for-update* is used to specify the FOR UPDATE clause in a select statement which is used by Oracle to lock the selected records. If *for-update* is `t` then a plain "FOR UPDATE" clause is generated. This locks all retrieved records, waiting for the

locks to become available. If *for-update* is `:nowait` then a "FOR UPDATE NOWAIT" clause is generated. This locks all the retrieved records, or otherwise returns with error ora-00054 which causes Lisp to signal a `sql-temporary-error`. If *for-update* is a string then it should specify a column to be locked and a clause "FOR UPDATE OF *for-update*" is generated. If *for-update* is a list then the elements of the list should be strings each specifying a column to be locked, except that the last element of the list may be `:nowait`. A clause locking multiple columns is generated, waiting for the locks according to whether `:nowait` was supplied. For an example see the section "Locking" on page 266.

The function `select` is common across both the functional and object-oriented SQL interfaces. If *selections* refers to View Classes then the `select` operation becomes object-oriented. This means that `select` returns a list of View Class instances, and `slot-value` becomes a valid SQL operator for use within the *where* clause.

In the View Class case, a second equivalent `select` call will return the same View Class instance objects. If *refresh* is true, then existing instances are updated if necessary, and in this case you might need to extend the hook `instance-refreshed`. Any join slots defined using *retrieval :deferred* will be recomputed the next time they are accessed. The default value of *refresh* is `nil`.

SQL expressions used in the `select` function are specified using the square bracket syntax, once this syntax has been enabled using `enable-sql-reader-syntax`.

## Examples

The following is a potential query and result:

```
(select [person_id] [surname] :from [person])
=> ((111 "Brown") (112 "Jones") (113 "Smith"))
```

In the next example, the *flatp* argument is set to `t`, and the result is a simple list of surname values:

*This chapter applies to the Enterprise Edition only*

```
(select [surname] :from [person] :flatp t)
=> ("Brown" "Jones" "Smith")
```

In this example data in the attribute `largenum`, which is of a vendor-specific large numeric type, is returned to Lisp as strings:

```
(sql:select [largenum :string] :from [my-table])
```

In this example the second column of `some_table` is a date that we want to return as a string:

```
(sql:select [*]
 :from [some_table]
 :result-types '(nil :string))
```

In this example we see that a time/date field value is returned as an integer. We then use Common Lisp to decode that universal time, and finally query the database again, forcing the return value to be a string formatted by the database:

```
CL-USER 219 > (sql:select [MyDate]
 :from [MyTable]
 :flatp t)
(3313785600)
("MYDATE")

CL-USER 220 > (decode-universal-time (car *))
0
0
0
4
1
2005
1
NIL
0

CL-USER 221 > (sql:select [MyDate :string]
 :from [MyTable]
 :flatp t)
("2005-01-04 00:00:00")
("MYDATE")
```

Finally this code gets the first 1KB of data from the first LOB returned by a query on an Oracle table containing a column of type LOB:

```
(let* ((array
 (make-array 1024
 :element-type '(unsigned-byte 8)))
 (lobs (sql:select [my-lob-column :input-stream]
 :from [mytable] :flatp t)))
 (read-sequence array (car lobs)))
```

## set-prepared-statement-variables *Function*

Summary Sets the values of the bind variables in a prepared-statement.

Package `sql`

Signature `set-prepared-statement-variables prepared-statement &key  
database values => prepared-statement`

Arguments `prepared-statement`  
                   A prepared-statement.

`database` A database or `nil`.

`values` A list.

Description The function `set-prepared-statement-variables` sets the values of the bind variables in the prepared-statement `prepared-statement` to the objects in the list given by `values`. The length of `values` must equal the number of bind-variables in the prepared-statement (that is, the supplied or computed count in `prepare-statement`). If `database` is supplied, then the prepared-statement is (re)associated with that database.

*This chapter applies to the Enterprise Edition only*

If *database* is not supplied and the statement is not associated with a database yet, `set-prepared-statement-variables` associates it with the default database `*default-database*`. If the statement was already associated and *database* is `nil`, the association does not change.

`set-prepared-statement-variables` returns the prepared-statement.

See also `prepare-statement`  
`destroy-prepared-statement`

## **simple-do-query** *Macro*

Summary Repeatedly binds a variable to the results of a query, optionally binds another variable to the column names, and executes a body of code within the scope of these bindings.

Package `sql`

Signature `simple-do-query (values-list query &key names-list database not-inside-transaction get-all) &body body =>`

Arguments `values-list` A variable.  
`query` A database query or a prepared-statement containing a query.  
`names-list` A variable, or `nil`.  
`database` A database.  
`not-inside-transaction` A generalized boolean.  
`get-all` A generalized boolean.  
`body` A Lisp code body.

Values None.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The macro <b>simple-do-query</b> repeatedly executes <i>body</i> within a binding of <i>values-list</i> to the attributes of each record resulting from <i>query</i>.</p> <p>If a variable <i>names-list</i> is supplied, then it is bound to a list of the column names for the query during the execution of <i>body</i>. The default value of <i>names-list</i> is <b>nil</b>.</p> <p><b>simple-do-query</b> returns no values.</p> <p>The default value of <i>database</i> is <b>*default-database*</b>.</p> <p><i>not-inside-transaction</i> and <i>get-all</i> may be useful when fetching many records through a connection with <i>database-type</i> <b>:mysql</b>. Both of these arguments have default value <b>nil</b>. See the section “Special considerations for iteration functions and macros” on page 260 for details.</p> |
| Example     | <pre>(sql:simple-do-query   (person-details [select [Surname] [ID] :from [person]]     :names-list xx)   (format t "~&amp;~A: ~A, ~A: ~A~%"     (first xx)     (first person-details)     (second xx)     (second person-details))) =&gt; SURNAME: Brown, ID: 2 SURNAME: Jones, ID: 3 SURNAME: Smith, ID: 4</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Package     | <code>sql</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Signature   | <code>sql &amp;rest args =&gt; sql-expression</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Arguments   | <code>args</code> A set of expressions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Values      | <code>sql-expression</code> A SQL expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description | The function <code>sql</code> generates SQL from a set of expressions given by <code>args</code> . Each argument to <code>sql</code> is translated into SQL and then the <code>args</code> are concatenated with a single space between each pair. The rules for translation into SQL, based on the type of each individual argument <code>x</code> , are as follows:<br><br><code>string =&gt; (format nil "'~A'" x)</code><br><code>nil =&gt; "NULL"</code><br><code>symbol =&gt; (symbol-name x)</code><br><code>number =&gt; (princ-to-string x)</code><br><code>list =&gt; (format nil "(~{~A~^,~})" (mapcar #'sql x))</code><br><code>vector =&gt; (format nil "~{~A~^,~}" (map 'list #'sql x))</code><br><code>sql-expression =&gt; x</code><br><br>Any other symbol => <code>error</code> |
| See also    | <code>sql-expression</code><br><code>sql-operation</code><br><code>sql-operator</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Description  | The condition class <code>sql-database-error</code> is used to signal errors in the database interface that Common SQL uses. |

*This chapter applies to the Enterprise Edition only*

**sql-error-error-id** returns the primary error identifier. On ODBC the value is a string. On Oracle it is some number, the "v2 return code" in the Cursor Data Area.

**sql-error-secondary-error-id** returns the secondary error identifier. On ODBC this is the error code from the underlying database. On Oracle that is the "v4 return code" (also known as "return code") in the Cursor Data Area, which is the useful code.

**sql-error-database-message** is a string (maybe `nil`) that came back from the foreign code.

Notes      ODBC drivers for Oracle return the "v4 return code" as the underlying database code. Therefore in the event of an error on connection to an Oracle database, **sql-error-secondary-error-id** always returns the "v4 return code" whether the connection is through ODBC.

## \***sql-enlarge-static\*** *Variable*

Package     **sql**

Initial Value    **100000**

Description    The amount to enlarge static memory by before loading database code. This is an optimization of static memory fragmentation, useful for some databases. It is ignored when loading Oracle.

Notes      \***sql-enlarge-static\*** is applicable in LispWorks for UNIX only (not LispWorks for Linux, FreeBSD, or x86/x64 Solaris).

| Initial Value   | <code>nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                               |          |
| Description     | Holds a pathname or list of libraries to override default database library loading. The value should be a pathname or a list.<br><br>If its value is a pathname, it is prepended to a list of relative pathnames in the same manner that the supplied environment variable (for example <code>ORACLE_HOME</code> ) would be. If its value is a list, then it is assumed to be a complete list of full library names which are loaded verbatim. |          |
| Notes           | <code>*sql-libraries*</code> is applicable only on Unix/Linux.                                                                                                                                                                                                                                                                                                                                                                                 |          |

**\*sql-loading-verbose\*** *Variable*

|               |                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------|
| Initial Value | <code>nil</code>                                                                                                         |
| Description   | The variable <code>*sql-loading-verbose*</code> controls the verbosity of messages while loading the database libraries. |
| Notes         | <code>*sql-loading-verbose*</code> is applicable only on Unix.                                                           |

| <i>inop1</i>  | An infix operator with non-boolean result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |           |              |             |                                    |             |                        |             |                                      |              |                                            |              |                                           |             |                                                         |               |                                                           |
| <i>inop2</i>  | An infix operator that returns a boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |           |              |             |                                    |             |                        |             |                                      |              |                                            |              |                                           |             |                                                         |               |                                                           |
| <i>left</i>   | Argument to be placed on the left of an infix operator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |           |              |             |                                    |             |                        |             |                                      |              |                                            |              |                                           |             |                                                         |               |                                                           |
| <i>rights</i> | Arguments to be placed on the right of an infix operator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |           |              |             |                                    |             |                        |             |                                      |              |                                            |              |                                           |             |                                                         |               |                                                           |
| Values        | <i>sql-result</i> A SQL expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |           |              |             |                                    |             |                        |             |                                      |              |                                            |              |                                           |             |                                                         |               |                                                           |

*This chapter applies to the Enterprise Edition only*

Description     The function `sql-operation` takes an operator and its arguments, and returns a SQL expression.

`(sql-operation op args)`

is shorthand for

`(apply (sql-operator op) args).`

The pseudo operator `sql-function` allows an arbitrary function *name* to be passed. In this case, *name* is put in the SQL expression using `princ`, and *args* are given as arguments.

The pseudo operators `sql-boolean-operator` and `sql-operator` generate SQL that calls an infix operator with *left* on the left and *rights* on the right separated by spaces. Use `sql-boolean-operator` for SQL infix operators that return a boolean and use `sql-operator` for any other SQL infix operator.

Notes        The pseudo operator `sql-operator` should not be confused with the Common SQL function `sql-operator`.

Example      The following code, uses `sql-operation` to produce a SQL expression.

```
(sql-operation 'select
 (sql-expression :table 'foo :attribute 'bar)
 (sql-expression :attribute 'baz)
 :from (list
 (sql-expression :table 'foo)
 (sql-expression :table 'quux))
 :where
 (sql-operation 'or
 (sql-operation '>
 (sql-expression :attribute 'baz)
 3)
 (sql-operation 'like
 (sql-expression :table 'foo :attribute 'bar)
 "SU%")))
```

The following SQL expression is produced.

```
#<SQL-QUERY: " (SELECT FOO.BAR,BAZ FROM FOO,QUUX
 WHERE ((BAZ > 3) OR (FOO.BAR LIKE 'SU%'))) ">
```

The following code illustrates use of the pseudo operator  
**sql-function**:

```
(sql-operation 'sql-function "TO_DATE" "03/06/99"
 "mm/DD/RR")
```

The following SQL expression is produced.

```
#<SQL-VALUE-EXP "TO_DATE('03/06/99','mm/DD/RR') ">
```

| Description | <p>The function <code>sql-stream</code> returns the broadcast stream used for recording SQL commands or results traffic.</p> <p><code>type</code> can be either <code>:commands</code> or <code>:results</code>, and specifies whether to return the broadcast stream for commands or results traffic.</p> <p>The default value of <code>type</code> is <code>:commands</code>. The default value of <code>database</code> is the value of <code>*default-database*</code>.</p> <p>Note that SQL traffic can appear on <code>*standard-output*</code> as well as on <code>stream</code>. See <code>add-sql-stream</code> for details.</p> |                                                          |

| Description  | <p>The condition class <code>sql-temporary-error</code> is used to signal an error that results from other users using the same database. This can be a table lock, but also running out of various resources.</p> |                  |

*This chapter applies to the Enterprise Edition only*

It means the code can work without change, once the other users stop using the database.

## **sql-timeout-error** *Condition*

Package      **sql**

Superclasses    **sql-connection-error**

Description     The condition class **sql-timeout-error** is used to signal an error due to the time out of some operation.

## **sql-user-error** *Condition*

Package      **sql**

Superclasses    **simple-error**

Description     The condition class **sql-user-error** is used to signal errors in Lisp code.

See also      **sql-database-error**

## **standard-db-object** *Class*

Package      **sql**

Superclasses    **standard-object**

Description     The class **standard-db-object** implements View Classes.

See also      **def-view-class**

| start-sql-recording   | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                   |            |                       |             |

| Description           | <p>The function <code>start-sql-recording</code> starts recording SQL traffic, potentially to multiple streams. The traffic recorded can be the commands, the results, or both commands and results.</p> <p>By default the output appears only <code>*standard-output*</code>. You can modify the broadcast list of recording streams using <code>add-sql-stream</code> and <code>delete-sql-stream</code>.</p> <p><code>type</code> is one of <code>:commands</code>, <code>:results</code> or <code>:both</code>. It determines whether SQL commands traffic, results traffic or both is recorded.</p> <p>The default value of <code>type</code> is <code>:commands</code>. The default value for <code>database</code> is the value of <code>*default-database*</code>.</p> |                   |            |                       |             |

|             | <i>Function</i>                                                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | A predicate for the existence of a table.                                                                                                               |
| Package     | <code>sql</code>                                                                                                                                        |
| Signature   | <code>table-exists-p table &amp;key database owner =&gt; result</code>                                                                                  |
| Arguments   | <code>table</code> A potential table name.<br><code>database</code> A database.<br><code>owner</code> <code>nil</code> , <code>:all</code> or a string. |
| Values      | <code>result</code> A boolean.                                                                                                                          |
| Description | The function <code>table-exists-p</code> determines whether there is a table named <code>table</code> in database <code>database</code> .               |

*This chapter applies to the Enterprise Edition only*

If `owner` is `null`, only user-owned tables are considered. This is the default.

If *owner* is :all, all tables are considered.

If `owner` is a string, this denotes a username and only tables owned by `owner` are considered.

The default value of *database* is **\*default-database\***.

| Values      | <i>instance</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | The updated View Class instance. |
| Description | <p>The generic function <code>update-instance-from-records</code> updates the values in the slots of the View Class instance <i>instance</i> using the data in the database <i>database</i>.</p> <p><i>database</i> defaults to the database that <i>instance</i> is associated with, or the value of <code>*default-database*</code>. If <i>instance</i> is associated with a database, then <i>database</i> must be that same database.</p> <p>The argument <i>slot</i> is the CLOS slot name; the corresponding column names are derived from the View Class definition.</p> |                                  |

The update is not recursive on joins. Join slots (that is, slots with `:db-kind :join`) are updated, but the joined objects are not updated.

## update-objects-joins *Function*

Summary      Updates the remote join slots.

Signature      `update-objects-joins objects &key slots force-p class-name max-len`

Arguments      `objects`      A list of database objects.

`slots`      A list of slot names, or `t`.

`force-p`      A boolean.

`class-name`      The class of the objects, or `nil`.

`max-len`      A non-negative integer, or `nil`.

Description      The function `update-objects-joins` updates the remote join slots, that is those slots defined without `:retrieval :immediate`.

This is an optimization function which can improve the efficiency of an application by reducing the number of queries of the database. For each slot, it queries the database using the data from all the objects, and then assigns the appropriate value to each object.

`objects` is a list of database objects. If `class-name` is non-`nil`, then all the database objects are of this class. If `class-name` is `nil`, then all the database objects are of the class of the first database object in the list `objects`.

If `objects` is `nil`, then `update-objects-joins` does nothing.

*class-name* specifies a class containing all the database objects in the list *objects*. If *class-name* is `nil` (the default) then the class of the first database object is used.

*slots* provides a list of the names of slots to update. Each of these slots should be a remote join slot (as defined above).

*slots* can also be `t`, meaning update all the remote join slots. The default value of *slots* is `t`.

*force-p* controls whether to force the update of all values in the objects. If *force-p* is `nil`, then slots which are already are not updated. The default value of *force-p* is `t`.

*max-len*, if non-nil, is a maximum number of objects from which to use data in a single query. If the length of the list *objects* is greater than *max-len* then `update-objects-joins` performs multiple queries using the data from no more than *max-len* objects in each query. This is useful if the DBMS may reject large queries, but it will increase the number of queries and hence reduce overall performance to some extent. The default value of *max-len* is the value of the variable

`*default-update-objects-max-len*`.

## **update-records** *Function*

Summary      Changes the values of fields in a table.

Package      `sql`

Signature      `update-records table &key attributes values av-pairs where database =>`

Arguments      `table`      A database table.

`attributes`      A set of columns.

| Description | The generic function <code>update-records-from-instance</code> updates the records in <i>database</i> represented by <i>instance</i> . If the instance is already associated with a database, that database is used, and <i>database</i> is ignored. If <i>instance</i> is not yet associ- |                              |

*This chapter applies to the Enterprise Edition only*

ated with a database, a record is created for *instance* in the appropriate table of *database* and the instance becomes associated with that database.

`update-records-from-instance` only updates the records from the base slots of *instance* - it does not look at the join slots.

| Description     | The generic function <code>update-record-from-slot</code> updates an individual data item in the column represented by <i>slot</i> . The <i>database</i> is only used if <i>instance</i> is not yet associated with any database, in which case a record is created in <i>database</i> . Only <i>slot</i> is initialized in this case; other columns in the underlying database receive default values. The argument <i>slot</i> is the CLOS slot name; the corresponding column names are derived from the View Class definition. |                 |                              |             |         |                 |             |

|             | <i>slot</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | A slot name.                     |
| Values      | <i>instance</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | The updated View Class instance. |
| Description | <p>The generic function <b>update-slot-from-record</b> updates the value in the slot <i>slot</i> of the View Class instance <i>instance</i> using the records in the database.</p> <p><i>instance</i> must be associated with a database.</p> <p>The argument <i>slot</i> is the CLOS slot name; the corresponding column names are derived from the View Class definition.</p> <p>The update is not recursive on joins. Join slots (that is, slots with <code>:db-kind :join</code>) are updated, but the joined objects are not updated.</p> |                                  |

| <code>body</code>     | A set of Lisp expressions.                                                                                                                                                                                                                                                                                                                                                                                                     |                       |             |                   |                            |
| Values                | <code>results</code><br>The values returned by <code>body</code> .                                                                                                                                                                                                                                                                                                                                                             |                       |             |                   |                            |
| Description           | <p>The macro <code>with-transaction</code> executes <code>body</code> within a transaction for <code>database</code> (which defaults to <code>*default-database*</code>). The transaction is committed if the body finishes successfully (without aborting or throwing), otherwise the database is rolled back.</p> <p><code>with-transaction</code> returns the value or multiple values returned from <code>body</code>.</p> |                       |             |                   |                            |
| Example               | The following example shows how to use <code>with-transaction</code> to insert a new record, updates the department number of employes from 40 to 50, and removes employees whose salary is higher than 300,000. If an error occurs anywhere in the body and an <code>abort</code> or <code>throw</code> is executed, none of the updates are committed.                                                                       |                       |             |                   |                            |
|                       | <pre>(with-transaction   (insert-record :into [emp]                  :attributes '(x y z)                  :values '(a b c))   (update-records [emp]                  :attributes [dept]                  :values 50                  :where [= [dept] 40])   (delete-records :from [emp]                  :where [&gt; [salary] 300000]))</pre>                                                                               |                       |             |                   |                            |
| See also              | <code>commit</code><br><code>rollback</code>                                                                                                                                                                                                                                                                                                                                                                                   |                       |             |                   |                            |

## The STREAM Package

This chapter describes the symbols available in the `stream` package that provide users with the functionality to define their own streams for use by the standard I/O functions.

This is discussed in detail in Chapter 20, “User Defined Streams”.

| buffered-stream | <i>Class</i>                                                                                                               |
|-----------------|----------------------------------------------------------------------------------------------------------------------------|
| Summary         | A stream class giving access to stream buffers.                                                                            |
| Package         | <code>stream</code>                                                                                                        |
| Superclasses    | <code>fundamental-stream</code>                                                                                            |
| Subclasses      | <code>lob-stream</code><br><code>string-stream</code><br><code>socket-stream</code>                                        |
| Initargs        | <code>:direction</code> One of <code>:input</code> , <code>:output</code> or <code>:io</code> . This argument is required. |

**:element-type** One of **base-char**, **simple-char** or **character**.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The class <b>buffered-stream</b> provides default methods for the majority of the functions in the User Defined Streams protocol. The default methods implement buffered I/O, requiring the user to define only the methods <b>stream-read-buffer</b>, <b>stream-write-buffer</b> and <b>stream-element-type</b> for each subclass of <b>buffered-stream</b>. You are at liberty to redefine other methods in subclasses as long as they obey the rules outlined here. For example it is usually desirable to implement methods on <b>stream-listen</b>, <b>stream-check-eof-no-hang</b> and <b>close</b> as well.</p> <p>The initargs are handled by the method <code>(method initialize-instance :after (buffered-stream))</code> as follows:</p> <p>Input and/or output buffers are created based on the value <i>direction</i>. There is no default value, and you must supply a value.</p> <p><i>element-type</i> determines the <b>stream-element-type</b> of the stream. The default is <b>base-char</b>. For binary streams, use <b>base-char</b>.</p> <p>All the methods in the User Defined Streams protocol are defined for <b>buffered-stream</b> as follows:</p> <ul style="list-style-type: none"> <li>• The methods on <b>stream-read-char</b>, <b>stream-read-line</b>, <b>stream-read-sequence</b>, <b>stream-unread-char</b>, <b>stream-read-char-no-hang</b>, <b>stream-clear-input</b> handle input from the buffer. They each call <b>stream-fill-buffer</b> to fill the empty buffer as required.</li> <li>• The methods on <b>stream-write-char</b>, <b>stream-write-string</b>, <b>stream-write-sequence</b>, <b>stream-clear-output</b>, <b>stream-finish-output</b>, <b>stream-force-output</b> and <b>stream-line-column</b> handle output to the buffer. They each call <b>stream-flush-buffer</b> to make the buffer empty as required.</li> </ul> |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- There are `:around` methods on `stream-listen` and `close` which handle the buffer.
- The methods on `input-stream-p`, `output-stream-p` return the appropriate values based on the value of the `:direction` initarg.
- The `open-stream-p` method returns true if `close` has not been called.

Example      See the extended example in `examples/streams/buffered-stream.lisp`

## **fundamental-binary-input-stream** *Class*

Summary      A stream class for binary input.

Package      `stream`

Superclasses    `fundamental-binary-stream`  
`fundamental-input-stream`

Subclasses     None.

Description     The class `fundamental-binary-input-stream` provides a class for generating customized binary input stream classes. A method for `stream-read-byte` should be provided when using this class.

See also      **fundamental-binary-stream**  
**fundamental-input-stream**  
**stream-read-byte**

## **fundamental-binary-output-stream** *Class*

Summary      A stream class for binary output.

Package      **stream**

Superclasses    **fundamental-binary-stream**  
**fundamental-output-stream**

Description     The class **fundamental-binary-output-stream** provides a class for generating customized binary output stream classes. A method for **stream-write-byte** should be provided.

See also      **fundamental-binary-stream**  
**fundamental-output-stream**  
**stream-write-byte**

## **fundamental-binary-stream** *Class*

Summary      A class for binary streams.

Package      **stream**

Superclasses    **fundamental-stream**

Subclasses     **fundamental-binary-input-stream**  
**fundamental-binary-output-stream**

Description     The class **fundamental-binary-stream** is the superclass of the binary input and output stream classes. A method for **stream-element-type** should be provided for instantiable subclasses of this class.

See also      **fundamental-binary-input-stream**  
                 **fundamental-binary-output-stream**  
                 **fundamental-stream**  
                 **stream-element-type**

## **fundamental-character-input-stream** *Class*

Summary      A class that should be included in stream classes for character input.

Package      **stream**

Superclasses    **fundamental-character-stream**  
                 **fundamental-input-stream**

Subclasses     None.

Description     The class **fundamental-character-input-stream** provides default methods for generic functions used for character input, and should therefore be included by stream classes concerned with character input. The user can provide methods for these generic functions specialized on the user-defined class. Methods for other generic functions must be provided by the user.

There is an example in “Defining a new stream class” on page 276.

**stream-read-sequence**  
**stream-unread-char**

## **fundamental-character-output-stream** *Class*

**Summary** A class that should be included in stream classes for character output.

**Package** **stream**

**Superclasses** **fundamental-character-stream**  
**fundamental-output-stream**

**Subclasses** None.

**Description** The class **fundamental-character-output-stream** provides default methods for generic functions used for character output, and should therefore be included by stream classes concerned with character output. The user can provide methods for these generic functions specialized on the user-defined class. Methods for other generic functions must be provided by the user.

There is an example in “Defining a new stream class” on page 276.

## **fundamental-output-stream** *Class*

Summary      A class whose inclusion causes **output-stream-p** to return t.

Package      **stream**

Superclasses    **fundamental-stream**

Subclasses    **fundamental-binary-output-stream**  
**fundamental-character-output-stream**

Description      The class **fundamental-output-stream** is a superclass to the binary and character output classes. Its inclusion causes the generic function **output-stream-p** to return t.

| Arguments   | <code>stream</code>                                                                                                                                                                                                                                                                                                        | A stream.   |
|             | <code>column</code>                                                                                                                                                                                                                                                                                                        | An integer. |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                        | A boolean.  |
| Description | The generic function <code>stream-advance-to-column</code> writes enough blank spaces to <code>stream</code> to ensure that the next character is written at <code>column</code> . The generic function returns <code>t</code> if the operation is successful, or <code>nil</code> if it is not supported for this stream. |             |

This function is intended for use by `print` and `format ~t`. The default method uses `stream-line-column` and repeated calls to `stream-write-char` with a `#\Space` character, and returns `nil` if `stream-line-column` returns `nil`.

## stream-check-eof-no-hang

## *Generic Function*

**Summary**      Determines whether a stream is at end of file.

## Package stream

Signature `stream-check-eof-no-hang stream => result`

Arguments      *stream*      An input stream.

Values              *result*              nil or :eof.

**Description** The generic function `stream-check-eof-no-hang` determines if the data source of the stream is at end of file, without hanging.

*stream* should be an instance of a subclass of `buffered-stream`.

*result* is `:eof` if *stream* is at end of file and `nil` otherwise.

There is a built-in method specialized on `buffered-stream` which returns `:eof` in all cases.

## stream-clear-input

## *Generic Function*

**Summary**      **Implements** `clear-input`.

|             |                                                                                                                                                                                     |

| Description | <p>The generic function <code>stream-file-position</code> implements <code>file-position</code>.<br/> <code>stream-file-position</code> is called when <code>file-position</code> is called with one argument.<br/> <code>(setf stream:stream-file-position)</code> is called when <code>file-position</code> is called with two arguments.</p> <p>The return value is returned by <code>file-position</code>. For the setf function, this is a slight anomaly because setf functions normally return the new value. However in this case it should return the <code>success-p</code> value mandated by the ANSI Common Lisp standard.</p> <p>The default methods specialized on <code>stream</code> return <code>nil</code>.</p> |                                       |

**stream-fill-buffer** *Generic Function*

|         |                          |
|---------|--------------------------|
| Summary | Fills the stream buffer. |
| Package | <code>stream</code>      |

| Description | <p>The generic function <code>stream-fill-buffer</code> is called by the reading functions to fill an empty stream buffer from the underlying data source.</p> <p><code>stream</code> should be an instance of a subclass of <code>buffered-stream</code>.</p> <p><code>stream-fill-buffer</code> should block until some data is available or return false at end of file. If data is available, it should place it in a buffer, set the stream's input buffer, index and limit appropriately and return a true value. The existing stream buffer can be reused if desired but the index and limit must be updated. The buffer must be of type <code>simple-string</code>, whose element type matches that given when the stream was constructed.</p> <p>There is a built-in method specialized on <code>buffered-stream</code> which usually suffices. It calls <code>stream-read-buffer</code> with the whole buffer and returns false if this call returns 0. If not, the input index is set to 0 and the input limit is set to the value returned by <code>stream-read-buffer</code>.</p> |                        |

| Arguments   | <i>stream</i>              | An output stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Values      | <i>result</i>              | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description |                            | <p>The generic function <code>stream-flush-buffer</code> is called by the writing functions to flush a stream buffer to the underlying data sink.</p> <p><i>stream</i> should be an instance of a subclass of <code>buffered-stream</code>.</p> <p>Before returning, <code>stream-flush-buffer</code> must set the output index of <i>stream</i> so that more characters can be written to the buffer. If desired, the output buffer and limit can be set too.</p> <p>There is a built-in method specialized on <code>buffered-stream</code> which usually suffices. It calls <code>stream-write-buffer</code> with</p> |

the currently active part of the stream's output buffer and sets the output index to 0.

*result* is true if the buffer was flushed.

## **stream-force-output**                                  *Generic Function*

Summary      Implements **force-output**.

Package      **stream**

Signature      **stream-force-output stream => nil**

Arguments      **stream**                          A stream.

Values      **nil**

Description      The generic function **stream-force-output** implements **force-output**. The default method is on **fundamental-output-stream** and does nothing.

There is an example in “Stream output” on page 278.

## **stream-fresh-line**                                  *Generic Function*

Summary      Used by **fresh-line** to start a new line on a given stream.

Package      **stream**

Signature      **stream-fresh-line stream => bool**

|             |               |                                                                                                                                                                                                                                                              |

| Description |                                                                          | The generic function <b>stream-line-column</b> returns the column number where the next character will be written from <i>stream</i> , or <b>nil</b> if this is not meaningful for the stream. This function is used in the implementation of <b>print</b> and the <b>format ~t</b> directive. A method for this function must be defined for every character output stream class that is defined, although at its simplest it may be defined to always return <b>nil</b> . |

| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | A generalized boolean. |
| Description | <p>The generic function <code>stream-listen</code> is called to determine if there is data immediately available on the stream <code>stream</code>, without hanging.</p> <p><code>result</code> should be true if there is input, and <code>nil</code> otherwise (including at end of file).</p> <p>This method must be implemented for subclasses of <code>buffered-stream</code> that handle input.</p> <p>There is a built-in primary method specialized on <code>buffered-stream</code> which returns <code>nil</code>. There is a built-in <code>:around</code> method specialized on <code>buffered-stream</code> which checks for input in the buffer and calls the next method if the buffer is empty. Thus a primary method specialized on a subclass of <code>buffered-stream</code> need only check the underlying data source.</p> <p>The built-in method on <code>fundamental-input-stream</code> uses <code>stream-read-char-no-hang</code> and <code>stream-unread-char</code>. Most streams should define their own method as this is usually trivial and more efficient than the method provided.</p> |                        |

| Values                     | <code>result</code> | An integer or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                   |
| Description                |                     | The generic function <code>stream-output-width</code> is used by the pretty printer to determine the output width when <code>*print-right-margin*</code> is <code>nil</code> . It returns <code>result</code> , the integer width of <code>stream</code> in units of ems, or <code>nil</code> if the width is not known. The default method provided by <code>fundamental-stream</code> returns <code>nil</code> . |

| Summary                 |                     | A generic function used by <code>peek-char</code> that returns a character on a given stream without removing it from the stream buffer. |
| Package                 | <code>stream</code> |                                                                                                                                          |
| Signature               |                     | <code>stream-peek-char stream =&gt; result</code>                                                                                        |
| Arguments               | <code>stream</code> | A stream.                                                                                                                                |
| Values                  | <code>result</code> | A character or <code>:EOF</code> symbol.                                                                                                 |

|             |                                                                                                                                                                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The generic function <code>stream-peek-char</code> is used to implement <code>peek-char</code> , and corresponds to a peek-type of <code>nil</code> . The default method reads a character from the stream without removing it from the stream buffer, by using <code>stream-read-char</code> and <code>stream-unread-char</code> . |

## stream-read-byte *Generic Function*

**Summary** A generic function used by `read-byte` to read an integer or `:eof` symbol from a binary stream.

## Package stream

Signature **stream-read-byte** *stream* => *result*

**Arguments**      *stream*      An input stream.

Values            *result*            An integer or :eof.

**Description** The generic function `stream-read-byte` is used by `read-byte`, and returns either an integer read from the binary stream specified by `stream`, or the keyword `:eof`.

A method must be implemented for all binary subclasses of `buffered-stream` that handle input. A typical implementation will call `stream-read-char` and convert the character to an integer using `char-code`.

A method should be defined for a subclass of `fundamental-binary-input-stream`.

## **stream-read-char-no-hang**

## *Generic Function*

|             |                                                                                                                               |                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| Summary     | Returns either a character from the stream, an :eof if the end-of-file is reached, or nil if no input is currently available. |                                             |
| Package     | <b>stream</b>                                                                                                                 |                                             |
| Signature   | <b>stream-read-char-no-hang</b>                                                                                               | <b>stream =&gt; result</b>                  |
| Arguments   | <b>stream</b>                                                                                                                 | An input stream.                            |
| Values      | <b>result</b>                                                                                                                 | Either a character, an :EOF symbol, or nil. |
| Description | The generic function <b>stream-read-char-no-hang</b> implements <b>read-char-no-hang</b> . It returns either a character read |                                             |

from the stream, or `:eof` if end-of-file is reached, or `nil` if no input is available. The default method provided by `fundamental-character-input-stream` simply calls `stream-read-char` which is sufficient for file streams, but interactive streams should define their own method.

## **stream-read-sequence**

### *Generic Function*

**Summary**     Reads a number of items from a stream into a sequence.

**Package**     **stream**

**Signature**     **stream-read-sequence stream sequence start end => index**

**Arguments**     **stream**     A stream.

**sequence**     A sequence.

**start**       An integer.

**end**       An integer.

**Values**     **index**     An integer.

**Description**     The generic function **stream-read-sequence** reads from *stream* into *sequence*. Elements from the *start* of *sequence* are replaced by elements from *stream* until *end* in *sequence* or the end-of-file in *stream* is reached. The index of the first element in *sequence* that is not replaced is returned.

A default method is provided by **fundamental-character-input-stream** which makes repeated calls to **stream-read-char** and uses **(setf elt)** to insert characters into *sequence*. A default method is provided by **fundamental-binary-input-stream** that makes repeated calls to **stream-read-byte** and also uses **(setf elt)** to insert bytes into *sequence*. Note that this may lead to error if the sequence is of inappropriate type.

**stream-start-line-p** *Generic Function*

|             |                                                                                                                                                   |            |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| Summary     | A generic function that returns <b>t</b> if the stream is positioned at the beginning of a line.                                                  |            |
| Package     | <b>stream</b>                                                                                                                                     |            |
| Signature   | <b>stream-start-line-p</b> <i>stream</i> => <i>result</i>                                                                                         |            |
| Arguments   | <i>stream</i>                                                                                                                                     | A stream.  |
| Values      | <i>result</i>                                                                                                                                     | A boolean. |
| Description | The generic function <b>stream-start-line-p</b> returns <b>t</b> if <i>stream</i> is positioned at the beginning of a line, and <b>nil</b> other- |            |

wise. It is permissible to define a method that always returns `nil`.

Note that although a value of 0 from `stream-line-column` also indicates the beginning of a line, there are cases where `stream-start-line-p` can be meaningfully implemented and `stream-line-column` cannot. For example, for a window using variable-width characters the column number is not very meaningful, whereas the beginning of a line has a clear meaning.

The default method for `stream-start-line-p` on class `fundamental-character-output-stream` uses `stream-line-column`. Therefore, if this is defined to return `nil`, a method should be provided for either `stream-start-line-p` or `stream-fresh-line`.

| Signature   | <b>stream-unread-char stream character =&gt; nil</b>                                                                                                                                                                            |              |
| Arguments   | <i>stream</i>                                                                                                                                                                                                                   | A stream.    |
|             | <i>character</i>                                                                                                                                                                                                                | A character. |
| Values      | <b>nil</b>                                                                                                                                                                                                                      |              |
| Description | The generic function <b>stream-unread-char</b> undoes the last call to <b>stream-read-char</b> , as in <b>unread-char</b> . Every subclass of <b>fundamental-character-input-stream</b> must define a method for this function. |              |
| See also    | <a href="#"><b>fundamental-character-input-stream</b></a>                                                                                                                                                                       |              |

## **stream-write-buffer** *Generic Function*

|           |                                                    |                                                       |
|-----------|----------------------------------------------------|-------------------------------------------------------|
| Summary   | Writes a part of stream's buffer.                  |                                                       |
| Package   | <b>stream</b>                                      |                                                       |
| Signature | <b>stream-write-buffer stream buffer start end</b> |                                                       |
| Arguments | <i>stream</i>                                      | An output stream.                                     |
|           | <i>buffer</i>                                      | A stream buffer.                                      |
|           | <i>start, end</i>                                  | Bounding indexes for a subsequence of <i>buffer</i> . |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The generic function <code>stream-write-buffer</code> is called by <code>stream-flush-buffer</code> to write the region of the buffer bounded by <code>start</code> and <code>end</code> to the stream's underlying data sink.</p> <p><code>stream</code> should be an instance of a subclass of <code>buffered-stream</code>.</p> <p>This method must be implemented for subclasses of <code>buffered-stream</code> that handle output.</p> |
| See also    | <p><code>buffered-stream</code></p> <p><code>stream-flush-buffer</code></p>                                                                                                                                                                                                                                                                                                                                                                     |

## **stream-write-byte** *Generic Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| Summary     | A generic function used by <code>write-byte</code> to write an integer to a binary stream.                                                                                                                                                                                                                                                                                                                                                                 |             |
| Package     | <code>stream</code>                                                                                                                                                                                                                                                                                                                                                                                                                                        |             |
| Signature   | <code>stream-write-byte stream integer =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                                                 |             |
| Arguments   | <code>stream</code>                                                                                                                                                                                                                                                                                                                                                                                                                                        | A stream.   |
|             | <code>integer</code>                                                                                                                                                                                                                                                                                                                                                                                                                                       | An integer. |
| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                        | An integer. |
| Description | <p>The generic function <code>stream-write-byte</code> is used by <code>write-byte</code>, and writes the integer <code>integer</code> to the binary stream specified by <code>stream</code>.</p> <p>A method must be implemented for all binary subclasses of <code>buffered-stream</code> that handle output. A typical implementation will convert the integer to a character using <code>code-char</code> and call <code>stream-write-char</code>.</p> |             |

A method should be defined for all subclasses of **fundamental-binary-output-stream**.

## **stream-write-char** *Generic Function*

Summary      Writes a character to a specified stream.

Package      **stream**

Signature      **stream-write-char stream character => character**

Arguments      **stream**      A stream.  
**character**      A character.

Values      **character**      A character.

Description      The generic function **stream-write-char** writes *character* to *stream*. Every subclass of **fundamental-character-output-stream** must have a method defined for this function.  
There is an example in “Stream output” on page 278.

See also      **fundamental-character-output-stream**

## **stream-write-sequence** *Generic Function*

Summary      Writes a subsequence of a sequence to a stream.

Package      **stream**

| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                | A string.   |
| Description | <p>The generic function <code>stream-write-string</code> is used by <code>write-string</code> to write <i>string</i> to <i>stream</i>. The string can, optionally, be delimited by <i>start</i> and <i>end</i>.</p> <p>The default method provided by <code>fundamental-character-output-stream</code> uses repeated calls to <code>stream-write-char</code>.</p> <p>There is an example in “Stream output” on page 278.</p> |             |

|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The macro <code>with-stream-input-buffer</code> allows access to the state of the input buffer for the given buffered stream.</p> <p><code>stream</code> should be an instance of a subclass of <code>buffered-stream</code>.</p> <p>Within the code <code>body</code>, the variables <code>buffer</code>, <code>index</code> and <code>limit</code> are bound to the buffer of <code>stream</code>, its current index and the limit of the buffer. Setting <code>buffer</code>, <code>index</code> or <code>limit</code> will change the values in the stream <code>stream</code> but note that other changes to these values (for example, by calling other stream functions) will not affect the values bound within the macro. See the example for a typical use which shows how this restriction can be handled.</p> <p>The buffer is always of type <code>simple-string</code>. The <code>stream-element-type</code> of <code>stream</code> depends on how it was constructed.</p> <p>The index is the position of the next element to be read from the buffer and the limit is the position of the element after the end of the buffer. Therefore there is no data in the buffer when <code>index</code> is greater than or equal to <code>length</code>.</p> |
| Example     | This example function returns a string with exactly four characters read from a buffered stream. If <code>end-of-file</code> is reached before four characters have been read, it returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## with-stream-output-buffer

*Macro*

Summary      Allows access to the output buffer.

Package      **stream**

Signature      **with-stream-output-buffer** (*buffer index limit*) **stream &body body** => *result*

Arguments      *buffer, index, limit*

### Variables

*stream*      An output stream

*body*      Code

Values      *result*      The value returned by body.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Summary   | Allows control over which generation objects are allocated in, in 64-bit LispWorks.          |                                                                                                                                              |
| Package   | <code>system</code>                                                                          |                                                                                                                                              |
| Signature | <code>apply-with-allocation-in-gen-num what gen-num func &amp;rest args =&gt; results</code> |                                                                                                                                              |
| Arguments | <i>what</i>                                                                                  | One of the keywords <code>:cons</code> , <code>:symbol</code> , <code>:function</code> , <code>:non-pointer</code> and <code>:other</code> . |
|           | <i>gen-num</i>                                                                               | An integer in the inclusive range [0,7], or <code>nil</code> .                                                                               |
|           | <i>func</i>                                                                                  | A function designator.                                                                                                                       |

|             |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>args</i>    | The arguments passed to <i>func</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Values      | <i>results</i> | The values returned from the call to <i>func</i> with <i>args</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Description |                | <p>The function <code>apply-with-allocation-in-gen-num</code> applies the function <i>func</i> to <i>args</i> such that objects of allocation type <i>what</i> are allocated in generation <i>gen-num</i>, in 64-bit Lisp-Works.</p> <p>See also the keyword <code>:allocation</code> to <code>make-array</code>, which catches the most common cases.</p> <p>It is probably quite rare that it is useful to use this function, unless the function allocates a lot, and you are certain that every object that is allocated of the allocation type is long-lived, which is normally difficult to tell.</p> |
| Notes       |                | <ol style="list-style-type: none"> <li>Allocation of interned symbols is controlled separately by <code>*symbol-alloc-gen-num*</code>.</li> <li>In 32-bit LispWorks the argument <i>what</i> is ignored and the effect is like that of the macro <code>allocation-in-gen-num</code>.</li> </ol>                                                                                                                                                                                                                                                                                                             |

## **atomic-pop** *Macro*

Summary      Like **pop**, but does the operation atomically.

Package      **system**

Signature     **atomic-pop** *place => element*

Arguments    *place*      One of the specific set of places defined for low level atomic operations.

Values        *element*     An object.

Description     The macro **atomic-pop** is the same as **cl:pop**, but is guaranteed atomic for a suitable place.  
  
*place* must be one of the places described in “Low level atomic operations” on page 192, or expand to one of them.

                **low-level-atomic-place-p**

## **atomic-push** *Macro*

Summary      Like **push**, but does the operation atomically.

Package      **system**

Signature     **atomic-push** *new-value place => new-place-value*

Arguments    *new-value*     An object.

|             |                        |                                                                                                                                                                                                                                             |
|-------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>place</i>           | One of the specific set of places defined for low level atomic operations.                                                                                                                                                                  |
| Values      | <i>new-place-value</i> | A list (the new value of place).                                                                                                                                                                                                            |
| Description |                        | The macro <b>atomic-push</b> is the same as <b>c1:push</b> , but is guaranteed atomic for a suitable place.<br><br><i>place</i> must be one of the places described in “Low level atomic operations” on page 192, or expand to one of them. |
| Notes       |                        | In many cases the natural inverse of <b>push</b> is <b>delete</b> , but there is no way to do <b>delete</b> atomically, except by using a separate lock, which must also be held while doing the <b>push</b> .                              |
| See also    |                        | <b>atomic-pop</b><br><b>low-level-atomic-place-p</b>                                                                                                                                                                                        |

|             |               | <i>Type</i>                                                                                                 |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------|
| Summary     |               | The augmented string type.                                                                                  |
| Package     |               | <b>system</b>                                                                                               |
| Signature   |               | <b>augmented-string</b> <i>length</i>                                                                       |
| Arguments   | <i>length</i> | The length of the string (or *, meaning any).                                                               |
| Description |               | This is the string type that can hold any character. Equivalent to:<br><br><b>(vector character length)</b> |

|         |  | <i>Function</i>                            |
|---------|--|--------------------------------------------|
| Summary |  | Tests if an object is an augmented string. |

|             |                                                                                                 |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | The default file type of binary files.                                                                                                                                                                                                                                                                                                                                                                                                      |
| Package       | <code>system</code>                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Initial value | The initial value of <code>*binary-file-type*</code> depends on the host CPU and the LispWorks implementation. See “Naming conventions for FASL files” on page 416.                                                                                                                                                                                                                                                                         |
| Description   | <p>The variable <code>*binary-file-type*</code> is the file type that <code>load</code>, <code>load-data-file</code> and <code>require</code> recognize as a binary (FASL) file (in addition to any additional file types in <code>*binary-file-types*</code>).</p> <p>Normally you should not set <code>*binary-file-type*</code>. If you need to load files with another type, push that type on to <code>*binary-file-types*</code>.</p> |
| See also      | <code>*binary-file-types*</code><br><code>load-data-file</code>                                                                                                                                                                                                                                                                                                                                                                             |

**\*binary-file-types\*** *Variable*

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | A list of file types that are loaded as binary files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Package       | <code>system</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Initial value | <code>nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description   | <p>The variable <code>*binary-file-types*</code> contains a list of strings naming file types which <code>load</code>, <code>load-data-file</code> and <code>require</code> recognize as binary (FASL) files. FASL files are the output of <code>compile-file</code>, <code>dump-forms-to-file</code> or <code>with-output-to-fasl-file</code>.</p> <p>You need to add a type to this list if you want load such files but they have an extension which is different from the default (the value of <code>*binary-file-type*</code>).</p> |

**call-system** *Function*

|           |                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package   | <code>system</code>                                                                                                                                                                                                                                                       |
| Signature | <code>call-system command &amp;key current-directory wait shell-type =&gt; status</code>                                                                                                                                                                                  |
| Arguments | <p><i>command</i> A string, a list of strings, a simple-vector of strings, or <code>nil</code>.</p> <p><i>current-directory</i> A string. Implemented only on Microsoft Windows.</p> <p><i>wait</i> A boolean.</p> <p><i>shell-type</i> A string or <code>nil</code>.</p> |
| Values    | <i>status</i> The exit status of the invoked shell or process.                                                                                                                                                                                                            |

Description      `call-system` allows executables and DOS or Unix shell commands to be called from Lisp code. The output goes to standard output, as the operating system sees it. (This normally means `*terminal-io*` in LispWorks.)

If *command* is a string then it is passed to the shell as the command to run without any other arguments. The type of shell to run is determined by *shell-type* as described below.

If *command* is a list then it becomes the argv of a command to run directly, without invoking a shell. The first element is the command to run directly and the other elements are passed as arguments on the command line (that is, element 0 has its name in argv[0] in C, and so on).

If *command* is a simple vector of strings, the element at index 0 is the command to run directly, without invoking a shell. The other elements are the complete set of arguments seen by the command (that is, element 1 becomes argv[0] in C, and so on).

If *command* is `nil`, then the shell is run.

On Microsoft Windows, if *command* is a string, LispWorks hides the first window of the execution of the command, because that is the console that `cmd.exe` starts in a DOS window. If the command itself is a console application, you may want to see the console. In this case run the command as a direct command. To do this, pass a list or a vector as described above. Conversely, if you run a console application and do not want to see the console, pass the command as a string.

On Microsoft Windows *current-directory* is the *lpCurrentDirectory* argument passed to `CreateProcess`. If this is not supplied, the *pathname-location* of the *current-pathname* is passed.

If *wait* is true, `call-system` does not return until the process has exited. The default for *wait* is `t`.

On Unix/Linux/Mac OS X/FreeBSD, if *shell-type* is a string it specifies the shell. If *shell-type* is `nil` (the default) then the Bourne shell, `/bin/sh`, is used. The C shell may be obtained by passing `" /bin/csh"`.

On Microsoft Windows if *shell-type* is `nil` then `cmd.exe` is used on Windows 7, Windows Vista, Windows XP and Windows 2000 and `command.com` on Windows 98 and Windows ME.

`call-system` returns the exit status of the shell invoked to execute the command on Unix/Linux/Mac OS X, or the process created on Microsoft Windows.

Compatibility note The argument `:shell-type` is not implemented in LispWorks for Windows 4.4 and earlier, and `cmd.exe` is not used implicitly.

On Microsoft Windows, LispWorks 5.0 and later use *shell-type* `cmd.exe` (or `command.com`) by default when *command* is a string. In LispWorks 5.x the user may see a DOS command window in this case, but LispWorks 6.0 and later explicitly hide the DOS window. To call your command directly *command* should be a list, as in the last example below.

Example On Unix:

```
(call-system (format nil "adb ~a < ~a > ~a"
 (namestring a)
 (namestring b)
 (namestring c)))
```

On Microsoft Windows:

```
(sys:call-system "sleep 3" :wait t)

(sys:call-system '("notepad" "myfile.txt"))
```

| Arguments   | <i>command</i>               | A string, a list of strings, a simple-vector of strings, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|             | <i>current-directory</i>     | A string. Supported only on Microsoft Windows.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|             | <i>prefix</i>                | A string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|             | <i>show-cmd</i>              | A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|             | <i>output-stream</i>         | An output stream or <code>nil</code> , <code>t</code> or <code>:tty</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | <i>wait</i>                  | A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|             | <i>shell-type</i>            | A string. Supported only on Unix/Linux/Mac OS X.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|             | <i>kill-process-on-abort</i> | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Values      | <i>status</i>                | The exit status of the invoked shell or process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description |                              | <p><code>call-system-showing-output</code> is an extension to <code>call-system</code> which allows output to be redirected. On Unix/Linux/Mac OS X this means it can be redirected to places other than the shell process from which the LispWorks image was invoked. <code>call-system-showing-output</code> therefore allows the user to, for example, invoke a shell command and redirect the output to the current Listener window.</p> <p>The argument <i>command</i> is interpreted as by <code>call-system</code>. On Microsoft Windows there is one difference: when <i>command</i> is a list or vector and the executable (that is, the first element of</p> |

the sequence *command*) in `call-system-showing-output` is not a GUI application, LispWorks hides the first window, which is the console that the executable will normally open. Note that for a non-direct command (that is, a string) LispWorks always hides the first window (which is the console) in both `call-system` and `call-system-showing-output`.

*prefix* is a prefix to be printed at the start of any output line. The default value is " ; ".

*show-cmd* specifies whether or not the *cmd* invoked will be printed as well as the output for that command. If *t* then *cmd* will be printed. The default value for *show-cmd* is *t*.

*output-stream* specifies where the output will be sent to. If *output-stream* is an output stream, the output is written to it. If *output-stream* is *t*, the output is written to `*standard-output*`. If *output-stream* is *nil*, the output is collected as a string, and returned as a second value from `call-system-showing-output`. If *output-stream* is `:tty`, `call-system-showing-output` behaves like `call-system`. The default value is `*standard-output*`.

If *wait* is true, `call-system-showing-output` does not return until the process has exited. If *nil*, `call-system-showing-output` returns immediately and no output is shown. The default for *wait* is *t*.

*shell-type* is a string naming a UNIX shell. The default is `"/bin/sh"`.

If *kill-process-on-abort* is true, then when `call-system-showing-output` is aborted the process is killed. The default value of *kill-process-on-abort* is *nil*.

`call-system-showing-output` returns the exit status of the shell invoked to execute the command on Unix/Linux/Mac OS X/FreeBSD, or the process created on Microsoft Windows.

Examples

On Linux:

```

CL-USER 1 > (sys:call-system-showing-output "pwd"
:prefix "***")
***pwd
***/amd/xanfs1-cam/u/ldisk/sp/lispsrc/v42/builds
0

CL-USER 2 > (sys:call-system-showing-output "pwd"
:prefix "&&" :show-cmd nil)
&&/amd/xanfs1-cam/u/ldisk/sp/lispsrc/v42/builds
0

```

On Microsoft Windows:

```

CL-USER 223 > (sys:call-system-showing-output
 "cmd /c type hello.txt"
 :prefix "***")
***cmd /c type hello.txt
***Hi there
0

CL-USER 224 > (sys:call-system-showing-output
 "cmd /c type hello.txt"
 :prefix "&&"
 :show-cmd nil)
&&Hi there
0

```

| Description |                 | <p>The functions <code>cdr-assoc</code> and <code>(setf cdr-assoc)</code> provide a generalized reference for elements in an association list. The arguments are all as specified for the Common Lisp function <code>assoc</code>. <code>cdr-assoc</code> and <code>(setf cdr-assoc)</code> read and write the <code>cdr</code> of an element in a manner consistent with the Common Lisp notion of places.</p> <p><code>cdr-assoc</code> returns the <code>cdr</code> of the first cons in the alist <i>alist</i> that satisfies the test, or <code>nil</code> if no element of <i>alist</i> matches.</p> <p><code>(setf cdr-assoc)</code> modifies the first cons in <i>alist</i> that satisfies the test, setting its <code>cdr</code> to <i>value</i>. If no element of <i>alist</i> matches, then <code>(setf cdr-assoc)</code> constructs a new cons <code>(cons item value)</code> and inserts it in the head of <i>alist</i>.</p> |
| Example     |                 | <pre>CL-USER 1 &gt; (defvar *my-alist*       (list (cons :foo 1)             (cons :bar 2))) *MY-ALIST*  CL-USER 2 &gt; (setf (sys:cdr-assoc :bar       *my-alist*) 3) 3  CL-USER 3 &gt; *my-alist* ((:FOO . 1) (:BAR . 3))</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Package     | <code>system</code>                                                                                                                                                                                                                                                                                                                                         |
| Description | This should always be set to <code>t</code> for a site (that is, network) license — the licensing mechanism does not work in any other circumstances. Do not set the variable otherwise, as it overrides any useful diagnostics which may accompany key-file errors. Not applicable to LispWorks for Linux, Windows, x86/x64 Solaris, FreeBSD or Macintosh. |

## **coerce-to-gesture-spec** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                               |

|             | <code>errorp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | A boolean.                                    |
| Values      | <code>gspec</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A Gesture Spec object                         |
| Description | <p>The function <code>coerce-to-gesture-spec</code> returns a Gesture Spec object <code>gspec</code> which can be used to represent the key-stroke indicated by <code>object</code>.</p> <p>If <code>object</code> is a Lisp character, then <code>gspec</code>'s data is one of the known Gesture Spec keywords, or its <code>char-code</code>, and <code>gspec</code>'s modifiers contains its <code>char-bits</code> attribute mapped onto the values <code>gesture-spec-control-bit</code> etc.</p> <p>If <code>object</code> is a keyword, then it must be one of the known Gesture Spec keywords and becomes <code>gspec</code>'s data. <code>gspec</code>'s modifiers is 0.</p> |                                               |

If *object* is a string, then `coerce-to-gesture-spec` expects it to be a sequence of modifier key names separated by the `-` character, followed by a single character or a character name as returned by `name-char` or the name of one of the known Gesture Spec keywords. Then `gspec` contains the corresponding Gesture Spec keyword or `char-code` in its `data`, and the modifier keys are represented in its *modifiers*.

If *object* is a Gesture Spec object, it is simply returned.

`coerce-to-gesture-spec` does not create wild gesture specs.

#### Examples

```
(sys:coerce-to-gesture-spec #\Control-C)
=>
#S(SYSTEM::GESTURE-SPEC :DATA 67 :MODIFIERS 2)

CL-USER 8 > (sys:coerce-to-gesture-spec #\Control-\c)
=>
#S(SYSTEM::GESTURE-SPEC :DATA 99 :MODIFIERS 2)

(sys:coerce-to-gesture-spec :F10)
=>
#S(SYSTEM::GESTURE-SPEC :DATA :F10 :MODIFIERS 0)

(sys:coerce-to-gesture-spec "Ctrl-C")
=>
#S(SYSTEM::GESTURE-SPEC :DATA 67 :MODIFIERS 2)

(sys:coerce-to-gesture-spec "Shift-F10")
=>
#S(SYSTEM::GESTURE-SPEC :DATA :F10 :MODIFIERS 1)
```

| Description | <p>The macro <code>compare-and-swap</code> compares the value in <i>place</i> with <i>compare</i>, and if they are the same (by <code>eq</code>), stores the <i>new-value</i> in <i>place</i>.</p> <p><code>compare-and-swap</code> returns non-nil if the store occurred, or <code>nil</code> if the store did not occur.</p> <p><i>place</i> must be one of the places described in “Low level atomic operations” on page 192, or expand to one of them.</p> <p>The operation is guaranteed to be atomic.</p> |                                                                            |

|             | <i>flag-name</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | A string.          |
| Description | <p>The function <code>copy-preferences-from-older-version</code> copies uses preferences from one part of the registry to another.</p> <p><i>old-path</i> and <i>new-path</i> are the paths of preferences for the old and the new version, corresponding to the paths that were passed to (<code>setf product-registry-path</code>).</p> <p><i>flag-name</i> is a name of the flag to use to record in the registry that the copy is already done. <i>flag-name</i> must be a valid registry value name on Microsoft Windows, and a valid filename on all other platforms. The default value of <i>flag-name</i> is the string "<code>copied-old-preferences</code>".</p> <p><code>copy-preferences-from-older-version</code> performs several checks:</p> <ol style="list-style-type: none"> <li>1. It checks if it already copied to <i>new-path</i> in the current session, and if so does nothing.</li> <li>2. It checks if the <i>flag-name</i> entry exists, and if so it does nothing.</li> <li>3. It checks if another call to <code>copy-preferences-from-older-version</code> is already executing (in another thread), and if so it just waits for the other call to finish.</li> </ol> <p>Then if all the checks above indicate that copying is still needed, <code>copy-preferences-from-older-version</code> copies the values from the tree below <i>old-path</i> to a tree below <i>new-path</i>. It traverses the entire tree below <i>old-path</i>, and checks each key to see if it has any values.</p> |                    |

For a key that has values, it checks if the key exists under *new-path*, and if the key exists it does not copy any of the values for this key, though it still traverses and maybe copies its subkeys. If the key does not exist under *new-path*, it creates the key and copies the values.

Because it makes checks before doing any work, `copy-preferences-from-older-version` is an inexpensive call that can be used freely.

|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| Summary     | Returns the amount of allocated data in a generation in 64-bit LispWorks.                                                                                                                                                                                      |             |
| Package     | <code>system</code>                                                                                                                                                                                                                                            |             |
| Signature   | <code>count-gen-num-allocation gen-num &amp;optional include-lower-generations</code>                                                                                                                                                                          |             |
| Arguments   | <p><i>gen-num</i>      An integer between 0 and 7, inclusive.<br/><i>include-lower-generations</i><br/>                  A generalized boolean.</p>                                                                                                            |             |
| Values      | <i>allocation</i>                                                                                                                                                                                                                                              | An integer. |
| Description | The function <code>count-gen-num-allocation</code> returns the amount of allocated data in generation <i>gen-num</i> . If <i>include-lower-generations</i> is non-nil, the returned value <i>allocation</i> also includes the data in the younger generations. |             |
| Notes       | <code>count-gen-num-allocation</code> is implemented only in 64-bit LispWorks. It is not relevant to the Memory Management                                                                                                                                     |             |

API in 32-bit implementations, where you can use `room-values` instead.

### **\*debug-initialization-errors-in-snap-shot\*** *Variable*

Summary      Controls use of the snapshot debugger.

Package      `system`

Initial value      `t`

Description      The variable `*debug-initialization-errors-in-snap-shot*` controls whether, in an image which is configured to start the LispWorks IDE automatically, an error during initialization is handled and displayed in a snapshot debugger after the IDE starts.

If the value of `*debug-initialization-errors-in-snap-shot*` is `nil` LispWorks behaves like LispWorks 5.0 and previous versions. That is, it attempts to enter the command line debugger.

### **default-eol-style** *Function*

Summary      Provides a default end of line style for a file.

Package      `system`

Signature      `default-eol-style pathname ef-spec buffer length => new-ef-spec`

Arguments      `pathname`      Pathname identifying location of `buffer`.

`ef-spec`      An external format spec.

`buffer`      A buffer whose contents are examined.

|             |                    |                                                                                                                                                                                      |
|-------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>length</i>      | Length (an integer) up to which <i>buffer</i> should be examined.                                                                                                                    |
| Values      | <i>new-ef-spec</i> | A new external format spec created by merging <i>ef-spec</i> with the encoding that was found.                                                                                       |
| Description |                    | Merge <i>ef-spec</i> with (:default :eol-style :crlf) on Microsoft Windows, (:default :eol-style :lf) on UNIX/Linux/Mac OS X. This is usually used as the last function on its list. |

## \*default-stack-group-list-length\* *Variable*

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | The size of the stack cache.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Package       | system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Initial Value | 10                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description   | <p>This variable determines the maximum size of the stack cache.</p> <p>Process stacks are cached and reused. When a process dies, its stack is put in the stack cache for future reuse if there are currently less than *default-stack-group-list-length* stacks in the cache. Therefore if your application repeatedly creates and discards more than 10 processes you should consider increasing the value of this variable.</p> <p>Note that stacks are allocated in generation 2, hence a program with a high turnover of processes may need to call (gc-generation t) periodically unless all the stacks of dead processes are reused.</p> |

The default stack size is 64KB on all 32-bit LispWorks x86 platforms.

## **define-atomic-modify-macro** *Macro*

Summary An atomic version of `define-modify-macro`.

Package `system`

Signature `define-atomic-modify-macro name lambda-list function &optional doc-string => name`

Arguments `name` A symbol.

`lambda-list` A `define-modify-macro` lambda list.

`function` A symbol.

`doc-string` A string, not evaluated.

Values `name` A symbol.

Description The macro `define-atomic-modify-macro` has the same syntax as `cl:define-modify-macro`, and performs a similar operation.

The resulting macro `name` can be used only on one of the specific set of places defined for low level atomic operations as listed in “Low level atomic operations” on page 192. The macro `name` reads the value of the `place`, calls the function `function`, and then writes the result of the function call if the value in `place` has not changed since it was first read. If that value did change, the operation is repeated until it succeeds.

Note that this means:

1. The function *function* may be called more than once for each invocation of the defined macro. Therefore *function* should not have any side effects.
2. *function* must be thread-safe, because it may run concurrently in several threads if the defined macro *name* is used from several threads simultaneously.
3. It is possible in principle for the value to change more than once between reading the *place* and writing the new value. This may end up resetting the value in *place* to its original value, and hence the operation will succeed. This is equivalent to the code being invoked after the last change, unless *function* itself looks at *place*, which may cause inconsistent results.

## **define-top-loop-command** *Macro*

Summary Defines a top level loop command.

Package `system`

Signature `define-top-loop-command name-and-options lambda-list form*`  
`name-and-options ::= name`

| `(name option*)`

`option ::= (:aliases alias*)`

| `(:result-type result-type)`

Arguments `name` A keyword naming the command.

`alias` A keyword naming an alias for the command.

`lambda-list` A destructuring lambda list.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>result-type</i> One of the symbols <b>values</b> , <b>eval</b> and <b>nil</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description | <p>The macro <b>define-top-loop-command</b> defines a top level loop command called <i>name</i> which takes the parameters specified by <i>lambda-list</i>. If <b>&amp;whole</b> is used in <i>lambda-list</i> then the variable will be bound to a list containing the whole command line, including the command name, but the command name is not included in <i>lambda-list</i> otherwise.</p> <p>If any aliases are specified in <i>option</i>, these keywords will also invoke the command.</p> <p>When the command is used, each form is evaluated in sequence with the variables from <i>lambda-list</i> bound to the subsequent forms on the command line.</p> <p>If <i>result-type</i> is <b>values</b> (the default), then the values of the last form will be returned to the top level loop.</p> <p>If <i>result-type</i> is <b>eval</b>, then the value of the last form should be a form and is evaluated by the top level loop as if it had been entered at the prompt.</p> <p>If <i>result-type</i> is <b>nil</b>, then the last form should return two values. If the second value is <b>nil</b> then the first value is treated as a list of values to returned to the top level loop. If the second value is non-nil then the first value should be a form and is evaluated by the top level loop as if it had been entered at the prompt.</p> |
| Notes       | For details of pre-defined top level loop commands, enter <b>:?</b> at the Listener prompt.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Example     | <p>Given this definition:</p> <pre>(define-top-loop-command (:lave                            (:result-type eval)) (form)                            (reverse form))</pre> <p>then the command line</p> <pre>:lave (1 2 list)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

will evaluate the form (`list 2 1`).

Here are definitions for two commands both of which will run `apropos`:

```
(define-top-loop-command (:apropos-eval
 (:result-type eval))
 (&rest args)
 ` (apropos ,@args))

(define-top-loop-command :apropos-noeval (&rest args)
 (apply 'apropos args))
```

The first one will evaluate the arguments before calling `apropos` whereas the second one will just pass the forms, so

```
:apropos-noeval foo
```

will find all the symbols containing the string `foo`, whereas

```
(setq foo "bar")
```

```
:apropos-eval foo
```

will find all the symbols containing the string `bar`.

## **detect-eol-style** *Function*

**Summary** Detects the end of line style of a file.

**Package** `system`

**Signature** `detect-eol-style pathname ef-spec buffer length => new-ef-spec`

**Arguments** `pathname` Pathname identifying location of `buffer`.

`ef-spec` An external format spec.

`buffer` A buffer whose contents are examined.

`length` Length (an integer) up to which `buffer` should be examined.

|             |                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | Extends the notion of space to include more than just the space character.                                                                                                                                                                        |
| Package       | <code>system</code>                                                                                                                                                                                                                               |
| Initial value | <code>nil</code>                                                                                                                                                                                                                                  |
| Description   | When this variable is true, the concept of “space” is extended from just <code>#\Space</code> to include other appropriate characters. The default is <code>nil</code> , for ANS compliance, but we recommend that you set it to <code>t</code> . |

This variable controls how the format directives `~:C` and `~:@C` output graphic characters which have an empty glyph. When this variable is `t`, all such characters are output using the name:

```
(format nil "~:C" #\No-break-space) -> "No-Break-
Space"
(format nil "~:C" (code-char #x3000)) -> "Ideographic-
Space"
```

When false, only one such character is output using the name:

```
(format nil "~:C" #\Space) -> "Space"
(format nil "~:C" #\No-break-space) -> " "
(format nil "~:C" (code-char #x3000)) -> " "
```

It also affects `whitespace-char-p`.

See also [extended-character-p](#)

## **\*file-encoding-detection-algorithm\*** *Variable*

Summary List of functions to call to work out an encoding.

Package `system`

Initial value  
`(find-filename-pattern-encoding-match`  
`find-encoding-option`  
`detect-unicode-bom`  
`locale-file-encoding)`

Description Functions on this list take four arguments—the pathname of the file; an external format spec; a vector of element-type `(unsigned-byte 8)` which contains the first bytes of the file; and a non-negative integer which is the maximum extent of buffer to be searched. This length argument is 0 in the case that the file does not exist, or the direction is `:output`. They return an external format spec, which normally is either `ef-`

*spec* unmodified, or the result of merging *ef-spec* with another external format spec via `merge-ef-specs`.

**Example** If you want `open` and so on, when opening a file for input, to inspect the attribute line and then fall back to a default if no attribute line is found, then set the variable to this value:

```
(find-encoding-option locale-file-encoding)
```

There are further examples in “Guessing the external format” on page 305.

**See also** `find-filename-pattern-encoding-match`  
`find-encoding-option`  
`detect-unicode-bom`  
`detect-japanese-encoding-in-file`  
`guess-external-format`  
`locale-file-encoding`

## file-encoding-resolution-error *Condition*

**Summary** An error type to signal when an external file format cannot be deduced.

**Package** `system`

**Superclasses** `error`

**Initargs** `:ef-spec` An external format specification.

**Description** An error type signalled when `open`, `load` or `compile-file` fail to detect an external format to use.

The *ef-spec* slot contains the incomplete external format specification argument constructed by `guess-external-format`.

**See also** `guess-external-format`

**\*file-eol-style-detection-algorithm\*** *Variable*

|             | <i>ef-spec</i>                                                                                                                                                                                                                                                                                                                                                                                                      | An external format spec.                                                                                                                                                 |  |  |  |
|             | <i>buffer</i>                                                                                                                                                                                                                                                                                                                                                                                                       | A buffer whose contents are examined.                                                                                                                                    |  |  |  |
|             | <i>length</i>                                                                                                                                                                                                                                                                                                                                                                                                       | Length (an integer) up to which <i>buffer</i> should be examined.                                                                                                        |  |  |  |
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                       | The result of reading the value returned from the <code>encoding</code> or <code>external-format</code> option as a Lisp expression in the <code>keyword</code> package. |  |  |  |
| Description | <p>Looks in the file options (EMACS-style <code>-*-</code> line) for an option called <code>encoding</code> or <code>external-format</code>, with value <i>value</i>.</p> <p>If found, it reads <i>value</i> as a Lisp expression in the <code>keyword</code> package and merges <i>ef-spec</i> with <i>value</i> and returns the result as <i>result</i>. Thus it does not override a supplied <i>ef-spec</i>.</p> |                                                                                                                                                                          |  |  |  |

## gen-num-segments-fragmentation-state *Function*

|             |                                                                                                                                    |                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Summary     | Shows the fragmentation state in a generation in 64-bit Lisp-Works.                                                                |                        |
| Package     | <code>system</code>                                                                                                                |                        |
| Signature   | <code>gen-num-segments-fragmentation-state gen-num &amp;optional statics-too =&gt; fragmentation-state</code>                      |                        |
| Arguments   | <i>gen-num</i>                                                                                                                     | A number.              |
|             | <i>statics-too</i>                                                                                                                 | A generalized boolean? |
| Values      | <i>fragmentation-state</i><br><br>A list in which each element is a list of length 3.                                              |                        |
| Description | The function <code>gen-num-segments-fragmentation-state</code> shows the fragmentation state in a generation in 64-bit Lisp-Works. |                        |

`gen-num-segments-fragmentation-state` returns a list, where each element is a sub-list showing the fragmentation state in a segment. The sub-list is of the form

`(allocation-type allocated free)`

where `allocation-type` is the allocation type of the segment, `allocated` is the amount of allocated data in the segment, and `free` is the total size of free areas in the segment that cannot be easily used.

The ratio `free/allocated` is the ratio that is compared to the fragmentation threshold to decide whether to copy a segment when doing a marking GC with copying (see `set-blocking-gen-num` and `marking-gc`).

Allocation types `:cons-static`, `:non-pointer-static`, `:mixed-static`, `:other-big` and `:non-pointer-big` are included in the result only if `statics-too` is non-nil. The default value of `statics-too` is nil.

- Notes
1. The implementation of `set-blocking-gen-num` is intended to solve any fragmentation issues automatically.
  2. `gen-num-segments-fragmentation-state` is implemented only in 64-bit LispWorks. It is not relevant to the Memory Management API in 32-bit implementations, where `check-fragmentation` is available instead.
