Contents

Preface **xxxv**

1 Starting LispWorks 1

The usual way to start LispWorks	1
Passing arguments to LispWorks	1
Starting the Common LispWorks Graphical IDE	3
Using LispWorks with SLIME	3
Quitting LispWorks	4

2 The Listener 5

First use of the listener	5
Standard listener commands	6
The listener prompt	8

3 The Debugger 9

Entering the REPL debugger	10
Simple use of the REPL debugger	11
The stack in the debugger	12
REPL debugger commands	13
Debugger troubleshooting	22
Debugger control variables	23

4 The REPL Inspector 27

Describe	27
----------	----

Inspect	28
Inspection modes	30
5 The Trace Facility	37
Simple tracing	37
Tracing options	39
Example	46
Tracing methods	47
Trace variables	47
Troubleshooting tracing	49
6 The Advice Facility	51
Defining advice	52
Combining the advice	53
Removing advice	54
Advice for macros and methods	55
Examples	57
Advice functions and macros	60
7 Dspecs: Tools for Handling Definitions	61
Dspecs	61
Forms of dspecs	62
Dspec namespaces	63
Types of relations between definitions	67
Details of system dspec classes and aliases	68
Subfunction dspecs	70
Tracking definitions	71
Finding locations	72
Users of location information	73
8 Action Lists	79
Defining action lists and actions	80
Exception handling variables	80
Other variables	81
Diagnostic utilities	81
Examples	81
Standard Action Lists	83

9 The Compiler 85

- Compiling a function 86
- Compiling a source file 87
- Compiling a form 87
- How the compiler works 87
- Compiler control 88
- Declare, proclaim, and declaim 93
- Optimizing your code 94
- Compiler parameters affecting LispWorks 101

10 Storage Management 103

- Introduction 103
- Guidance for control of the storage management system 104
- Memory Management in 32-bit LispWorks 109
- Memory Management in 64-bit LispWorks 117
- Common Memory Management Features 122
- Assisting the garbage collector 123

11 The Profiler 125

- What the profiler does 125
- Setting up the profiler 126
- Running the profiler 127
- Profiler output 129
- Interpretation of profiling results 130
- Profiling pitfalls 130
- Profiling and garbage collection 131

12 Customization of LispWorks 133

- Introduction 133
- Configuration and initialization files 134
- Saving a LispWorks image 135
- Saved sessions 137
- Load and open your files on startup 140
- Customizing the editor 140
- Finding source code 142
- Controlling redefinition warnings 142
- Specifying the initial working directory 143

Using ! for :redo	143
Customizing LispWorks for use with your own code	143
Structure printing	144
Configuring the printer	144
13 LispWorks as a dynamic library	147
Introduction	147
Creating a dynamic library	148
Initialization of the dynamic library	149
Relocation	150
Multiprocessing in a dynamic library	151
Unloading a dynamic library	151
14 The Metaobject Protocol	153
Metaobject features incompatible with AMOP	153
Common problems when using the MOP	156
Implementation of virtual slots	157
15 Multiprocessing	165
Introduction to processes	165
The process programming interface	166
Atomicity and thread safety of the LispWorks implementation	176
Locks	179
Process Waiting	182
Synchronization between threads	185
Timers	189
Process properties	189
Native threads and foreign code	190
Low level atomic operations	192
16 Common Defsystem and ASDF	197
Introduction	197
Defining a system	198
Using ASDF	203
17 The Parser Generator	205
Introduction	205

Grammar rules	205
Functions defined by defparser	207
Error handling	208
Interface to lexical analyzer	208
Example	209
18 Dynamic Data Exchange	213
Introduction	213
Client interface	215
Server interface	219
19 Common SQL	223
Introduction	223
Initialization	227
Functional interface	234
Object oriented interface	242
Symbolic SQL syntax	247
Working with date fields	254
SQL I/O recording	256
Error handling in Common SQL	256
Using MySQL	258
Using Oracle	263
Oracle LOB interface	264
Using ODBC	274
20 User Defined Streams	275
Introduction	275
An illustrative example of user defined streams	275
21 TCP/IP socket communication and SSL	283
Running a server that accepts connections	283
Connecting to a server	284
Information about IP addresses	284
Waiting on a socket stream	284
Special considerations	284
Socket Stream SSL interface	285

22	Internationalization	297
	Introduction	297
	Character and String types	297
	String accessors	300
	String Construction	300
	External Formats	303
	External Formats and File Streams	304
	External Formats and the Foreign Language Interface	308
	Unicode character and string functions	308
23	LispWorks' Operating Environment	309
	The Operating System	309
	Site Name	309
	The Lisp Image	310
	The Command Line	310
	Address Space and Image Size	313
	Startup relocation	314
	Calling external programs	319
	Snapshot debugging of startup errors	320
	System message log	320
	Exit status	320
	Creating a new executable with code preloaded	320
	Universal binaries on Mac OS X	321
	User Preferences	322
	Special locations in the file system	323
	Accessing the Windows registry	325
	Pathname comparison on Mac OS X	326
24	64-bit LispWorks	329
	Introduction	329
	Heap size	330
	Architectural constants	331
	Speed	331
	Memory Management	331
	Float types	331
	External libraries	332

25 The CLOS Package 333

break-new-instances-on-access 333
break-on-access 334
class-extra-initargs 335
compute-class-potential-initargs 336
compute-discriminating-function 338
funcallable-standard-object 338
process-a-class-option 339
process-a-slot-option 341
set-clos-initarg-checking 344
set-make-instance-argument-checking 345
slot-boundp-using-class 346
slot-makunbound-using-class 347
slot-value-using-class 347
trace-new-instances-on-access 348
trace-on-access 349
unbreak-new-instances-on-access 352
unbreak-on-access 353
untrace-new-instances-on-access 353
untrace-on-access 354

26 The COMM Package 355

attach-ssl 355
connect-to-tcp-server 357
destroy-ssl 359
destroy-ssl-ctx 360
detach-ssl 360
do-rand-seed 361
ensure-ssl 362
get-host-entry 363
get-socket-address 366
get-socket-peer-address 367
get-verification-mode 367
ip-address-string 368
ipv6-address 369
ipv6-address-p 369
ipv6-address-scope-id 370
ipv6-address-string 370
make-ssl-ctx 371

open-tcp-stream 372
openssl-version 375
parse-ipv6-address 376
pem-read 378
read-dhparams 379
server-terminate 380
set-verification-mode 381
set-ssl-ctx-dh 383
set-ssl-ctx-options 384
set-ssl-ctx-password-callback 385
set-ssl-library-path 386
socket-error 387
socket-stream 387
socket-stream-address 392
socket-stream-ctx 393
socket-stream-peer-address 393
socket-stream-ssl 394
ssl-cipher-pointer 395
ssl-cipher-pointer-stack 395
ssl-closed 395
ssl-condition 396
ssl-ctx-pointer 396
ssl-error 396
ssl-failure 397
ssl-new 397
ssl-pointer 398

Preface

About this manual

This manual contains a user guide section (previously published separately as the *LispWorks User Guide*) and a reference section (previously the *LispWorks Reference Manual*).

User Guide section

The user guide section of this manual describes the main language-level features and tools available in LispWorks, and how to use them.

These chapters describe the central programming tools and features in LispWorks:

- Chapter 1, “Starting LispWorks” describes how to start LispWorks and supply command line arguments.
- Chapter 2, “The Listener” describes the read-eval-print loop (REPL) listener.
- Chapter 3, “The Debugger” describes the REPL debugger.
- Chapter 4, “The REPL Inspector” describes the REPL inspector.
- Chapter 5, “The Trace Facility” describes the tracer.
- Chapter 6, “The Advice Facility”.

- Chapter 7, “Dspecs: Tools for Handling Definitions” describes the naming system for Lisp definitions, and in particular how to locate these.
- Chapter 8, “Action Lists” describes how you can run code at various hook points.
- Chapter 9, “The Compiler” describes the compiler optimization qualities and some ways to optimize your code.
- Chapter 10, “Storage Management” covers the behavior (and for wizard level users, configuration) of the garbage collector.
- Chapter 11, “The Profiler” describes a tool for identifying bottlenecks impeding performance of your program.

The next chapter, Chapter 12, “Customization of LispWorks”, explains how to perform some commonly required customizations, such as controlling start-up appearance of LispWorks.

The remaining user guide chapters describe features of specialist interest:

- Chapter 13, “LispWorks as a dynamic library” describes how LispWorks operates as a DLL, .dylib or .so.
- Chapter 14, “The Metaobject Protocol” describes how the LispWorks MOP implementation differs from AMOP.
- Chapter 15, “Multiprocessing”, including locks.
- Chapter 16, “Common Defsystem and ASDF” describes how to use `defsystem` to combine a series of source files into a manageable project.
- Chapter 17, “The Parser Generator”.
- Chapter 18, “Dynamic Data Exchange” describes how to implement DDE functionality in your Microsoft Windows applications.
- Chapter 19, “Common SQL” explains how to use LispWorks to communicate with databases using SQL.
- Chapter 20, “User Defined Streams” provides an illustrative example showing how to define and implement your own streams.
- Chapter 21, “TCP/IP socket communication and SSL” describes the use of socket streams, including the Secure Sockets Layer (SSL).

- Chapter 22, “Internationalization” provides an overview of using international characters.
- Chapter 23, “LispWorks’ Operating Environment” explains how to find information about the Operating System and how LispWorks was started.
- Chapter 24, “64-bit LispWorks” outlines differences between 64-bit LispWorks and 32-bit LispWorks.

Please note that documentation for Graphics Ports is in the *LispWorks CAPI User Guide* and *LispWorks CAPI Reference Manual*.

Reference section

Most of the reference section is organized by package: each chapter contains reference material for the exported symbols in a given package. The chapters are organized alphabetically by package name.

Generally one chapter covers each package, but the `WIN32` package symbols are split into four chapters, and the last chapter contains reference material for C functions. Within each chapter, the symbols are organized alphabetically (ignoring non-alphanumeric characters that are common in Lisp symbols, such as *). The chapters are:

- Chapter 25, “The CLOS Package”, describes the LispWorks extensions to CLOS, the Common Lisp Object System.
- Chapter 26, “The COMM Package”, describes the functions providing the TCP/IP interface.
- Chapter 27, “The COMMON-LISP Package”, describes the LispWorks extensions to symbols in the `COMMON-LISP` package. You should refer to the Common Lisp Hyperspec, supplied in HTML format with LispWorks, for full documentation about standard Common Lisp symbols.
- Chapter 28, “The COMPILER Package”, describes symbols available in the `COMPILER` package.
- Chapter 29, “The DBG Package”, describes symbols available in the `DBG` package, used to configure the debugging information produced by LispWorks.

- Chapter 30, “The DSPEC Package”, describes the symbols available in the **DSPEC** package, which are used for naming and locating definitions.
- Chapter 31, “The EXTERNAL-FORMAT Package”, describes symbols available in the **EXTERNAL-FORMAT** package.
- Chapter 32, “The HCL Package”, describes symbols available in the **HCL** package.
- Chapter 33, “The LINK-LOAD Package”, describes symbols available in the **LINK-LOAD** package. It applies to LispWorks for UNIX only (not LispWorks for Linux, FreeBSD, or x86/x64 Solaris).
- Chapter 34, “The LISPWORKS Package”, describes symbols available in the **LISPWORKS** package.
- Chapter 35, “The MP Package”, describes symbols available in the **MP** package, giving you access to the multi-processing capabilities of LispWorks.
- Chapter 36, “The PARSERGEN Package”, describes symbols available in the **PARSERGEN** package, the LispWorks parser generator.
- Chapter 37, “The SERIAL-PORT Package” documents the Serial Port API. This is implemented only in LispWorks for Windows.
- Chapter 38, “The SQL Package” documents symbols used in accessing LispWorks ODBC and SQL functionality.
- Chapter 39, “The STREAM Package” documents the symbols available in the **STREAM** package that provide users with the functionality to define their own streams for use by the standard I/O functions.
- Chapter 40, “The SYSTEM Package”, describes symbols available in the **SYSTEM** package.
- Chapter 41, “Miscellaneous WIN32 symbols”, describes miscellaneous symbols available in the **WIN32** package. It applies only to LispWorks for Windows.
- Chapter 42, “The Windows registry API”, describes the Windows registry API. It applies only to LispWorks for Windows.

- Chapter 43, “The DDE client interface”, describes the Dynamic Data Exchange (DDE) client API. It applies only to LispWorks for Windows.
- Chapter 44, “The DDE server interface”, describes the Dynamic Data Exchange (DDE) server API. It applies only to LispWorks for Windows.
- Chapter 45, “Dynamic library C functions”, describes C functions available in LispWorks dynamic libraries.

Many of these reference chapters should be used in conjunction with corresponding chapters in the user guide section. Reference material for some aspects of LispWorks can be found in other manuals.

The LispWorks manuals

The LispWorks manual set comprises the following books:

- The Common Lisp Hyperspec contains the specification for Common Lisp itself.
- The *LispWorks User Guide and Reference Manual*—this book—describes the main language-level features and tools available in LispWorks, along with an extensive reference of the functions, macros, variables and classes organized by package. Where LispWorks extends the functionality of a Common Lisp symbol, this is mentioned in Chapter 27, “The COMMON-LISP Package”
- The *LispWorks IDE User Guide* describes the LispWorks IDE, the user interface for LispWorks. This is a set of windowing tools that let you develop and test Common Lisp code more easily and quickly.
- The *LispWorks Editor User Guide* describes the keyboard commands and programming interface to the LispWorks IDE editor tool.
- The *LispWorks CAPI User Guide* and the *LispWorks CAPI Reference Manual* describe the CAPI. This is a library of classes, functions, and macros for developing graphical user interfaces for your applications. The *LispWorks CAPI User Guide* is a tutorial guide to the CAPI, and the *LispWorks CAPI Reference Manual* is an in-depth reference text.

- The *LispWorks Foreign Language Interface User Guide and Reference Manual* explains how you can use C source code in applications developed using LispWorks.
- The *LispWorks Delivery User Guide* describes how you can deliver working, standalone versions of your LispWorks applications for distribution to your customers.
- *Developing Component Software with CORBA* describes how LispWorks can interoperate with other CORBA-compliant systems.
- The *LispWorks COM/Automation User Guide and Reference Manual* describes a toolkit for using Microsoft COM and Automation in Lisp-Works for Windows.
- The *LispWorks Objective-C and Cocoa Interface User Guide and Reference Manual* describes APIs for interfacing to Objective-C and Cocoa in Lisp-Works for Macintosh.
- The *KnowledgeWorks and Prolog User Guide* describes the LispWorks tool-kit for building knowledge-based systems. Common Prolog is a logic programming system written in Common Lisp.
- The *LispWorks Release Notes and Installation Guide* explains how to install LispWorks and start it running. It also contains Release Notes describing the new features in this release and any issues that could not be included in the other manuals.

The LispWorks manuals are all available in Portable Documentation Format (PDF). You can use Adobe Reader to browse the PDF documentation online or to print it. Adobe Reader is available for free download from Adobe's web site at www.adobe.com.

The LispWorks manuals are also available in HTML format. Commands in the **Help** menu of any of the LispWorks IDE tools give you direct access to the HTML documentation, using your web browser. Details of how to use these commands can be found in the *LispWorks IDE User Guide*.

Please let us know if you find any mistakes in the LispWorks documentation, or if you have any suggestions for improvements.

Other documentation

The LispWorks manuals do not attempt to describe Lisp itself. For definitive information on Common Lisp, including CLOS, consult the American National Standard X3.226 for Common Lisp. An HTML version of this document is supplied with LispWorks and can be accessed from the **Help** menu.

For information on CLOS, Sonya E. Keene's book *Object-Oriented Programming in Common Lisp: A Programmers' Guide* is very helpful. This book is published by Addison-Wesley.

For an account of Metaobject protocols as well as a detailed study of an implementation of CLOS see Kiczales, Rivieres and Bobrow, *The Art of the Meta-Object Protocol*, published by MIT Press, often referred to as AMOP. The LispWorks MOP mostly conforms chapters 5 & 6 of AMOP; the differences are mentioned here in Chapter 14, "The Metaobject Protocol".

Notation and conventions

Throughout this manual you will find references such as "... the LispWorks file `foo/bar.lisp` ...". This means a file `bar.lisp` in a subdirectory `foo` of the LispWorks library directory. You can obtain the full path of such a file by evaluating this form in your LispWorks image:

```
(sys:lispworks-file "foo/bar.lisp")
```

The LispWorks manuals follow the notation used in *Common Lisp: the Language* (2nd Edition).

Please note that your windows may differ in some respects from the illustrations given in the LispWorks manuals. This is because some details are controlled by the window manager that you are using, not by LispWorks itself.

1

Starting LispWorks

Firstly you need LispWorks installed as described in the Release Notes and Installation Guide.

1.1 The usual way to start LispWorks

On Windows and Mac OS X the simplest way to run LispWorks is that provided in the desktop environment. On Windows you can run LispWorks from the Start menu. On Mac OS X you can run LispWorks by clicking on the ringed "LW" icon in the Dock. On both these platforms you can create a shortcut to LispWorks and place it somewhere that is convenient for you, such as the Quick Start toolbar in Windows XP.

On Linux, FreeBSD and UNIX systems you start LispWorks by entering the name of the LispWorks executable at a shell prompt.

1.2 Passing arguments to LispWorks

Occasionally you may need to start LispWorks with certain arguments. This section describes the most frequent of these occasions.

1.2.1 Saving a new image

Note: If you use the LispWorks IDE, you may a saved session more convenient than saving an image as described in this section. See “Saved sessions” on page 137 for more information.

To save a new image "by hand", create a suitable file `save-config.lisp` as described in the section "Saving and testing the configured image" in the *LispWorks Release Notes and Installation Guide*. Such a file should load any desired configuration, modules and application code, and lastly call `save-image`.

Then you run LispWorks with a command line which passes your file as an build script.

On Mac OS X, run Terminal.app to get a shell, and enter a line like this at the prompt:

```
% lispworks-6-1-0-macos-universal -build /tmp/save-config.lisp
```

On Windows, run Command Prompt to get a DOS shell, and enter a line like this:

```
C:\Program Files\LispWorks>lispworks-6-1-0-x86-win32.exe -build  
C:\temp\save-config.lisp
```

On Linux, get a shell and enter a line like this:

```
% lispworks-6-1-0-x86-linux -build /tmp/save-config.lisp
```

On UNIX, get a shell and enter a line like this:

```
% lispworks-6-1-0-sparc-solaris -build /tmp/save-config.lisp
```

When the command exits, a new image has been saved. You can run this new image directly from the command line, or create a shortcut or symbolic link to make it convenient to run.

With all the command lines above, if you perform the task frequently, make a script or a shortcut containing the command line, and run that.

Note that `save-config.lisp` no longer needs to do `(load-all-patches)` because `-build` calls `load-all-patches` automatically in LispWorks 6.1. However, it does no harm if `save-config.lisp` does call `load-all-patches`.

1.2.2 Saving a console mode image

To save a LispWorks image which does not start the graphical IDE by default, make a script similar to `save-config.lisp` above, but where you call

```
(save-image "my-console-lispworks" :environment nil)
```

The resulting new image, `my-console-lispworks`, can be made to start the graphical IDE either by calling `env:start-environment` or by passing `-env` or `-environment` on the command line.

1.2.3 Bypassing initialization files

If you do not want to load your personal initialization file, for example to discover if behavior of LispWorks is due to some setting of yours, pass `-init -` on the command line.

To start LispWorks without loading either the personal or site initialization files, start it like this:

```
lispworks -init - -siteinit -
```

1.2.4 Other command line options

Other less commonly-used LispWorks command line arguments are described in “The Command Line” on page 310

1.3 Starting the Common LispWorks Graphical IDE

In LispWorks images shipped on the Windows, Mac OS X, Linux, x86/x64 Solaris and FreeBSD platforms, the IDE starts automatically by default.

If you have an image saved such that the IDE does not start by default, you can start the IDE by calling the function `env:start-environment`. Such an image is shipped for UNIX platforms.

1.4 Using LispWorks with SLIME

Download SLIME from <http://common-lisp.net/project/slime/>

1.4.1 Using the Professional/Enterprise Editions with SLIME

To use LispWorks with SLIME it is best to use an image which does not start the LispWorks IDE automatically. You can create such an image with LispWorks Professional or Enterprise Edition. Save it as `~/lw-console` as described in “Saving a non-GUI image with multiprocessing enabled” on page 137.

Configure Emacs to use "`~/lw-console`" as the value of `inferior-lisp-program` as shown in the SLIME README.

1.4.2 Using the Personal Edition with SLIME

Start LispWorks Personal Edition, which starts the LispWorks IDE automatically.

Execute these forms in the LispWorks IDE:

```
(load "/path/to/slime/swank-loader")
(swank-loader:init)
(swank:create-server :port 4005)
```

Inside Emacs, `Meta+X slime-connect`. Use the same port given above.

1.5 Quitting LispWorks

To quit LispWorks from the graphical IDE, use one of the following:

- The menu command **File > Exit** all platforms except Mac OS X.
- The menu command **LispWorks > Quit LispWorks** on Mac OS X.
- The key `Command+Q` on Mac OS X
- The key sequence `ctrl+x ctrl+c` in an editor-based tool such as the Editor or Listener
- A platform/window-manager-specific exit gesture such as clicking a close button on the Podium window
- Call the function `quit`.

To quit LispWorks when running in console mode or via SLIME, simply call `quit`.

2

The Listener

The listener is another name for the read-eval-print loop (REPL) which allows you to interactively evaluate Lisp forms and see their output and return values. Lisp programmers typically do incremental development and testing in a listener before saving the working code to disk.

This chapter describes the basic use of a LispWorks listener. You might access this in a terminal (Unix shell) or MS-DOS command window. Alternatively the LispWorks IDE contains a graphical Listener tool which runs a REPL and supports all the functionality described in this chapter, as well as its own graphical features. Please refer to the *LispWorks IDE User Guide* for details specific to the graphical Listener tool.

2.1 First use of the listener

LispWorks runs a top-level REPL on startup. The listener by default appears with a prompt. The name of the current package (that is, the value of `cl:*package*`) is printed followed by a positive integer, like this:

```
CL-USER 1 >
```

Enter a Lisp form after the prompt and press `Return`:

```
CL-USER 1 > (print 42)
```

```
42
42
```

```
CL-USER 2 >
```

The first ‘42’ printed is the output of the call to `print`. You see it here because output sent to `*standard-output*` is written to the listener.

The second ‘42’ printed is the return value of the call to `print`.

After the return value a new prompt appears. Notice that it contains ‘2’ after the package name: your successive inputs are numbered. You can now proceed to develop and test pieces of your application code:

```
CL-USER 2 > (defstruct animal species name weight)
ANIMAL

CL-USER 3 > (make-animal :species "Hippopotamus" :name "Hilda"
  :weight 42)
#S(ANIMAL :SPECIES "Hippopotamus" :NAME "Hilda" :WEIGHT 42)
```

2.2 Standard listener commands

Generally the listener simply evaluates Lisp forms that you enter. However a few keywords, described in the this section, are specially recognized as shortcut for common listener operations.

2.2.1 Standard top-level loop commands

`:redo`

Listener command

`:redo &optional command-identifier`

This option repeats a previous input. The *command-identifier* is either a number in the listener’s history list or a symbol or subform in the input to repeat. If *command-identifier* is not supplied, the last input is repeated.

`:get`

Listener command

`:get name command-identifier`

:get retrieves a previously-entered input from the listener's history and places it in the variable *name*. The *command-identifier* is the history list number of the input to be retrieved.

:use*Listener command*

:use new old &optional command-identifier

:use does a variant of a previous input. *old* matches a symbol or sub-form in the previous input, and is replaced with *new* to construct the new input. If supplied, *command-identifier* is the history list number of the input you want to modify.

:his*Listener command*

:his &optional n m

:his produces a list of the input history. If *n* is supplied it should be a positive integer: the last *n* inputs are shown. If *m* is also supplied it should be a positive integer greater than *n*, when inputs numbered *n* through *m* in the history are shown.

:bug-form*Listener command*

:bug-form subject &key filename

:bug-form prints a template bug report suitable for sending to Lisp Support. Supply a string *subject*. If you also supply *filename*, the report is printed to the file.

:help*Listener command*

:help

:help prints a brief listing of the available listener commands.

:?*Listener command*

: ?

`:?` is a synonym for `:help`.

2.2.2 Examples

```

CL-USER 4 > :redo
(MAKE-ANIMAL :SPECIES "Hippopotamus" :NAME ...)
#S(ANIMAL :SPECIES "Hippopotamus" :NAME "Hilda" :WEIGHT 42)

CL-USER 5 > :his

1: (PRINT 42)
2: (DEFSTRUCT ANIMAL SPECIES NAME ...)
3: (MAKE-ANIMAL :SPECIES "Hippopotamus" :NAME ...)
4: (MAKE-ANIMAL :SPECIES "Hippopotamus" :NAME ...)

CL-USER 5 > :get make-hilda 3

CL-USER 5 > make-hilda
(MAKE-ANIMAL :SPECIES "Hippopotamus" :NAME "Hilda" :WEIGHT 42)

CL-USER 6 > :use "Henry" "Hilda"
(MAKE-ANIMAL :SPECIES "Hippopotamus" :NAME ...)
#S(ANIMAL :SPECIES "Hippopotamus" :NAME "Henry" :WEIGHT 42)

CL-USER 7 > :bug-form "Too many hippos..." :filename "bug-
report.txt"

```

2.3 The listener prompt

The variable `*prompt*` controls the appearance of the listener prompt. See `*prompt*`, page 775 if you want to alter this.

If the default prompt contains a colon followed by a second positive integer then you are no longer in the top-level loop, but have entered the REPL debugger, as described in “The Debugger” on page 9.

3

The Debugger

The debugger is an interactive tool for examining and manipulating the Lisp environment. Within the debugger you have access to not only the interpreter, but also to a variety of debugging tools. The default behavior when any error occurs is to enter the debugger. Users can then trace backwards through the history of function calls to determine how the error arose. They may inspect and alter local variables of the functions on the execution stack, and possibly continue execution by invoking a pre-defined restart (if available) or by forcing any function invocation on the stack to return user-specified values.

When writing an application it is possible to prevent entry to the debugger when an error occurs, by creating condition handlers to take some appropriate action to recover without user intervention. It is also possible to use restarts to specify some default methods of error recovery. The debugger is entered whenever an error is signalled (via a call to `error` or `cerror`) and not handled by an error handler, or it can be explicitly invoked via a call to `break`.

You can use the debugger in REPL mode (that is, in the listener read-eval-print loop) or using the graphical Debugger tool in the LispWorks IDE. This chapter describes the REPL debugger; please refer to the *LispWorks IDE User Guide* for details about the graphical Debugger tool.

The compiler generates information necessary for the use of the debugger during compilation. You can opt for faster compilation, at the expense of

reducing the information available to the debugger, using `toggle-source-debugging`.

3.1 Entering the REPL debugger

The following is a simple example.

```
CL-USER 1 > (defun make-a-hippo (name weight)
  (if (numberp weight)
      (make-animal 'hippo name weight)
      (error "Argument to make-a-hippo not a number")))
MAKE-A-HIPPO

CL-USER 2 > (make-a-hippo "Hilda" nil)

Error: Argument to make-a-hippo not a number
1 (abort) return to level 0.
2 return to top loop level 0.
3 Destroy process.

Type :c followed by a number to proceed
CL-USER 3 : 1 >
```

The call to `error` causes entry into the debugger. The final prompt in the example contains a 1 to indicate that the top level of the debugger has been entered. The debugger can be entered recursively, and the prompt shows the current level. Once inside the debugger, you may use all the facilities available at the top-level in addition to the debugger commands.

The debugger may also be invoked by using the trace facility to force a break at entry to or exit from a particular function.

The debugger can also be entered by a keyboard interrupt. Keyboard interrupts are generated by the *break gesture*, which varies between the supported systems as follows:

Microsoft Windows	<code>Ctrl+Break</code>
GTK and Motif	<code>Meta+Ctrl+C</code>

Break if keyboard has that key. Note that PC keyboards do not have **Break**, only **Ctrl+Break**, which is different. See also `capi:set-interactive-break-features`.

Cocoa	Command+Control+, (comma). This is only supported on Mac OS X 10.4 and newer.
-------	--

When the break gesture is used, LispWorks attempts to find a busy process to break. If there is no obvious candidate and the LispWorks IDE is running, then it displays the Process Browser tool.

3.2 Simple use of the REPL debugger

Upon entering the debugger as a result of an error, a message describing the error is printed and a number of options to continue (called restarts) are presented. Thus:

```
CL-USER 6 > (/ 3 0)

Error: Division-by-zero caused by / of (3 0)
  1 (continue) Return a value to use
  2 Supply new arguments to use
  3 (abort) return to level 0.
  4 return to top loop level 0.
  5 Destroy process.

Type :c followed by a number to proceed

CL-USER 7 : 1 >
```

To select one of these restarts, enter `:c` (continue) followed by the number of the restart. So in the above example you could continue as follows:

```
CL-USER 7 : 1 > :c 2

Supply first number: 33

Supply second number: 11
3

CL-USER 8 >
```

There are two special restarts, a continue restart and an abort restart. These are indicated by the bracketed word continue or abort at their start. The continue restart can be invoked by typing :c alone. Similarly, the abort restart can be invoked by entering :a. So an alternative continuation of the division example would be:

```
CL-USER 7 : 1 > :c  
  
Supply a form to be evaluated and used: (+ 4 5)  
9
```

3.3 The stack in the debugger

The debugger allows you to examine the state of the execution stack. This consists of a sequence of frames representing active function invocations, special variable bindings, restarts, active catchers, active handlers and system-related code. In particular the execution stack has a call frame for each active function call (that is for each function that has been entered but from which control has not yet returned). The top of the stack contains the most recently created frames (and so the innermost calls), and the bottom of the stack contains the oldest frames (and so the outermost calls). You can examine a call frame to find the function's name, and the names and values of its arguments.

The function call frames displayed are affected by any `hcl:alias` and `hcl:invisible-frame` declarations. See `declare`, page 418 for the details.

Catch frames are established by using the special form `catch`, and exist to receive throws to the matching tag. Restart frames correspond to restarts that have been set up, and handler frames correspond to the error handlers currently active. Binding frames are formed when special variables are bound. Open frames are established by the system. By default only the catch frames and the call frames are displayed. However the remaining types of frame are displayed if you set the appropriate variables (see Section 3.6 on page 23).

Within the debugger there are commands to examine a stack frame, and to move around the stack. These are explained in the following section. Typing `:help` in the debugger also produces a command listing.

One of the most useful features is that you can access a local variable in the current frame simply by entering its name as shown in the backtrace. See step 7 in “Example debugging session” on page 21.

3.4 REPL debugger commands

This section describes commands specific to the debugger. In the debugger, you can also do anything that you can do in the top-level loop including evaluation of forms and the standard listener commands.

Upon entry to the debugger the implicit current stack frame is set to the top of the execution stack. The debugger commands allow you to move around the stack, to examine the current frame, and to leave the debugger. The commands are all keywords, and as such case-insensitive, but are shown here in lower case for clarity.

You can get brief help listing these commands by entering `:?` at the debugger prompt.

3.4.1 Backtracing

A backtrace is a list of the stack frames starting at the current frame and continuing down the stack. The backtrace thus displays the sequence by which the functions were invoked, starting with the most recent. For instance:

3 The Debugger

```
CL-USER 10 > (defun function-1 (a b c)
                  (function-2 (+ a b) c))
FUNCTION-1

CL-USER 11 > (defun function-2 (a b)
                  (function-3 (+ a b)))
FUNCTION-2

CL-USER 12 > (defun function-3 (a) (/ 3 (- 111 a)))
FUNCTION-3

CL-USER 13 > (function-1 1 10 100)

Error: Division-by-zero caused by / of (3 0)
1 (continue) Return a value to use
2 Supply new arguments to use
3 (abort) return to level 0.
4 return to top loop level 0.
5 Destroy process.

Type :c followed by a number to proceed

CL-USER 14 : 1 > :bq 10

SYSTEM::DIVISION-BY-ZERO-ERROR <- / <- FUNCTION-3
<- SYSTEM::*%APPLY-INTERPRETED-FUNCTION <- FUNCTION-2
<- SYSTEM::*%APPLY-INTERPRETED-FUNCTION <- FUNCTION-1
<- SYSTEM::*%APPLY-INTERPRETED-FUNCTION <- SYSTEM:::%INVOKE <-
SYSTEM::%EVAL

CL-USER 15 : 1 >
```

In the above example the command to show a quick backtrace was used (`:bq`). Instead of showing each stack frame fully, this only shows the function name associated with each of the call frames. The number 10 following `:bq` specifies that only the next ten frames should be displayed rather than continuing to the bottom of the stack.

:b

Debugger command

`:b &optional verbose m`

This is the command to obtain a backtrace from the current frame. It may optionally be followed by `:verbose`, in which case a fuller description of each frame is given that includes the values of the arguments to the

function calls. It may also be followed by a number (*m*), specifying that only that number of frames should be displayed.

:bq

Debugger command

:bq m

This produces a quick backtrace from the current position. Only the call frames are included, and only the names of the associated functions are shown. If the command is followed by a number then only that many frames are displayed.

3.4.2 Moving around the stack

On entry to the debugger the current frame is the one at the top of the execution stack. There are commands to move to the top and bottom of the stack, to move up or down the stack by a certain number of frames, and to move to the frame representing an invocation of a particular function.

:>

Debugger command

This sets the current frame to the one at the bottom of the stack.

:<

Debugger command

This sets the current frame to the one at the top of the stack.

:p

Debugger command

:p [m | fn-name | fn-name-substring]

By default this takes you to the previous frame on the stack. If it is followed by a number then it moves that number of frames up the stack. If it is followed by a function name then it moves to the previous call frame for that function. If it is followed by a string then it moves to the previous call frame whose function name contains that string.

:n *Debugger command*

:n [m | fn-name | fn-name-substring]

Similar to the above, this goes to the next frame down the stack, or *m* frames down the stack, or to the next call frame for the function *fn-name*, or to the next call frame whose function name contains *fn-name-substring*.

3.4.3 Miscellaneous commands

:v *Debugger command*

This displays information about the current stack frame. In the case of a call frame corresponding to a compiled function the names and values of the function's arguments are shown. Closure variables (either from an outer scope or used by an inner scope) and special variables are indicated by {closing} or {special} as in this session:

```

CL-USER 40 > (compile (defun foo (*zero* one two) (declare
(special *zero*)) (divider one *zero*) (list #'(lambda () one)
two)))
FOO
NIL
NIL

CL-USER 41 > (foo 0 1 2)

Error: Division-by-zero caused by / of (1 0).
1 (continue) Return a value to use.
2 Supply new arguments to use.
3 (abort) Return to level 0.
4 Return to top loop level 0.

Type :b for backtrace, :c <option number> to proceed, or :? for
other options

CL-USER 42 : 1 > :v
Call to FOO (offset 87)
 *ZERO*  {Special} : 0
 ONE      {Closing} : 1
 TWO          : 2

CL-USER 43 : 1 >

```

For an interpreted function the names and values of local variables are also shown.

If the value of an argument is not known (perhaps because the code has been compiled for speed rather than other considerations), then it is printed as the keyword `:dont-know`.

:l

Debugger Command

:l [m | var-name | var-name-substring]

By default this prints a list of the values of all the local variables in the current frame. If the command is followed by a number then it prints the value of the *m*'th local variables (counting from 0, in the order shown by the `:v` command). If it is followed by a variable name *var-name* then it prints the value of that variable (note that the same effect can be achieved by just entering the name of the variable into the Listener). If it

is followed by a string *var-name-substring* then it prints the value of the first variable whose name contains *var-name-substring*.

In all cases, * is set to the printed value.

:error

Debugger command

This reprints the message which was displayed upon entry to the current level of the debugger. This is typically an error message and includes several continuation options.

:cc

Debugger command

:cc &optional var

This returns the current condition object which caused entry to this level of the debugger. If an optional var is supplied then this must be a symbol, whose symbol-value is set to the value of the condition object.

:ed

Debugger command

This allows you to edit the function associated with the current frame. If you are using TAGS, you are prompted for a TAGS file.

:all

Debugger command

:all &optional flag

This option enables you to set the debugger option to show all frames (if flag is non-nil), or back to the default (if flag is nil). By default, flag is t.

:lambda

Debugger command

This returns the lambda expression for an anonymous interpreted frame. If the expression is not known, then it is printed as the keyword :dont-know

:func*Debugger command***:func &optional *disassemble-p***

This returns (and sets `*` to) the function object of the current frame. This is especially useful for the call frame of functions that are not the symbol function of some symbols, for example closures and method functions.

If *disassemble-p* is true, **:func** first disassembles the function, and then returns it and sets `*`. The default value of *disassemble-p* is `nil`.

:func is applicable only in call frames.

:if*Debugger command*

This command prints symbols from other packages corresponding to the symbol that was called, but could not be found, in the current package. Any such symbols are also offered as restarts when you first enter the debugger.

```
NEW 21 > (initialize-graphics-port)

Error: Undefined function INITIALIZE-GRAFICS-PORT called with
arguments ().

 1 (continue) Try invoking INITIALIZE-GRAFICS-PORT again.
 2 Return some values from the call to INITIALIZE-GRAFICS-PORT.
 3 Try invoking GRAPHICS-PORTS:INITIALIZE-GRAFICS-PORT with the
same arguments.
 4 Set the symbol-function of INITIALIZE-GRAFICS-PORT to the
symbol-function of GRAPHICS-PORTS:INITIALIZE-GRAFICS-PORT.
 5 Try invoking something other than INITIALIZE-GRAFICS-PORT
with the same arguments.
 6 Set the symbol-function of INITIALIZE-GRAFICS-PORT to
another function.
 7 (abort) Return to level 0.
 8 Return to top loop level 0.
```

Type `:c` followed by a number to proceed or type `:?` for other options

```
NEW 22 : 1 > :lf
Possible candidates are (GRAPHICS-PORTS:INITIALIZE-GRAFICS-PORT)
GRAPHICS-PORTS:INITIALIZE-GRAFICS-PORT
```

```
NEW 23 : 1 >
```

3.4.4 Leaving the debugger

You may leave the debugger either by taking one of the continuation options initially presented, or by explicitly specifying values to return from one of the frames on the stack.

:a *Debugger command*

This selects the **:abort** option from the various continuation options that are displayed when you enter the current level of the debugger.

:c *Debugger command*

:c &optional m

If this is followed by a number then it selects the option with that number, otherwise it selects the **:continue** option.

:ret *Debugger command*

:ret value

This causes *value* to be returned from the current frame. It is only possible to use this command when the current frame is a call frame. Multiple values may be returned by using the **values** function. So to return the values 1 and 2 from the current call frame, you could type

:ret (values 1 2)

:res *Debugger command*

:res m

Restarts the current frame. If *m* is **nil**, you are prompted for new arguments which should be entered on one line, separated by whitespace. If *m* is true or is not supplied, the original arguments to the frame are used.

:top *Debugger command*

Aborts to the top level of the debugger. A synonym is **:a :t**.

3.4.5 Example debugging session

This section presents a short interactive debugging session. It starts by defining a routine to calculate Fibonacci Numbers, and then erroneously calls it with a string.

1. First, define the `fibonacci` function shown below in a listener.

```
(defun fibonacci (m)
  (let ((fib-n-1 1)
        (fib-n-2 1)
        (index 2))
    (loop
      (if (= index m) (return fib-n-1))
      (incf index)
      (psetq fib-n-1 (+ fib-n-1 fib-n-2)
            fib-n-2 fib-n-1))))
```

2. Next, call the function as follows.

```
(fibonacci "turtle")
```

The system generates an error, since `=` expects its arguments to be numbers, and displays several continuation options, so that you can try to find out how the problem arose.

3. Type `:bq` at the debugger prompt to perform a quick backtrace. Notice that the problem is in the call to `fibonacci`.

Note that the calls to `*%apply-interpreted-function` in the backtrace occur because `fibonacci` is being interpreted.

You should have passed the length of the string as an argument to `fibonacci`, rather than the string itself.

4. Do this now, by typing the following form at the debugger prompt.

```
(length "turtle")
```

You intended to call `fibonacci` with the length of the string, but typed `in length` incorrectly. This takes you into the second level of the debugger. Note that the continuation options from your entry into the top level of the debugger are still displayed, and are listed after the new options. You can select any of these options.

5. Type `:a` to return to the top level of the debugger.

6. Type `:v` to display variable information about the current stack frame in the debugger.

The following output is displayed:

```
M : "turtle"
INDEX : 2
FIB-N-2 : 1
FIB-N-1 : 1
```

You need to set the value of the variable `m` to be the length of the string “turtle”, rather than the string itself.

7. Type in the form below.

```
(setq m (length "turtle"))
```

In order to get the original computation to resume using the new value of `m`, you still need to handle the original error.

8. Type `:error` to remind yourself of the original error condition you need to handle.

You can handle this error by returning `nil` from the call to `=`, which is the result that would have been obtained if `m` had been correctly set.

9. Type `:c` to invoke the continue restart, which in this case requires you to return a value to use.

10. When prompted for a form to be evaluated, type `nil`.

This causes execution to continue as desired, and you can obtain the final result with no further problems.

3.5 Debugger troubleshooting

Code which modifies the readtable case of the readtable can hinder debugger interaction. This is because standard commands entered as lowercase `:a` for example will not be recognized if the readtable case is `:preserve` or `:down-case`.

You can use `with-debugger-wrapper` together with `with-standard-io-syntax` to enable the debugger to recognize such input if the code in `body` should enter the debugger, like this:

```
(defun my-debugger-wrapper (func condition)
  (with-standard-io-syntax
    (funcall func condition)))

(dbg:with-debugger-wrapper
  'my-debugger-wrapper
  (let ((*readtable* (some-modified-readtable)))
    body))
```

3.6 Debugger control variables

common-lisp:*debug-io*	<i>Variable</i>
-------------------------------	-----------------

The value of this variable is the stream which the debugger uses for its input and output.

dbg:*debug-print-length*	<i>Variable</i>
---------------------------------	-----------------

The value to which `common-lisp:*print-length*` is bound during output from the debugger.

dbg:*debug-print-level*	<i>Variable</i>
--------------------------------	-----------------

The value to which `common-lisp:*print-level*` is bound during output from the debugger.

dbg:*hidden-packages*	<i>Variable</i>
------------------------------	-----------------

This variable should be bound to a list of packages. The debugger suppresses symbols from these packages (so, for example, it does not display call frames for functions in these packages).

dbg:*print-binding-frames*	<i>Variable</i>
-----------------------------------	-----------------

This variable controls whether binding frames are displayed by the debugger. The initial value is `nil`. The value can be set directly or by calling `dbg:set-debugger-options` which may be more convenient.

dbg:*print-catch-frames* *Variable*

This variable controls whether catch frames are displayed by the debugger. The initial value is `nil`. The value can be set directly or by calling `dbg:set-debugger-options` which may be more convenient.

dbg:*print-handler-frames* *Variable*

This variable controls whether handler frames are displayed by the debugger. The initial value is `nil`. The value can be set directly or by calling `dbg:set-debugger-options` which may be more convenient.

dbg:*print-restart-frames* *Variable*

This variable controls whether restart frames are displayed by the debugger. The initial value is `nil`. The value can be set directly or by calling `dbg:set-debugger-options` which may be more convenient.

dbg:*print-non-symbol-frames* *Variable*

This variable controls whether non-symbol frames are displayed by the debugger. The initial value is `nil`. The value can be set directly or by calling `dbg:set-debugger-options` which may be more convenient.

dbg:set-debugger-options *Function*

`dbg:set-debugger-options &key all bindings catchers hidden non-symbol
handler restarts invisible`

A call to `set-debugger-options` allows you to set the debugger printing control variables without having the inconvenience of setting each variable individually with a call to `setq` and without having to remember the names for each of the variables.

The keyword arguments refer to the debugger printing control variables as described below:

`:all` — affects the state of the `:all` command.

`:bindings` — `dbg:*print-binding-frames*`

```
:catchers — dbg:*print-catch-frames*
:hidden — dbg:*hidden-packages*
:non-symbol — dbg:*print-non-symbol-frames*
:handler — dbg:*print-handler-frames*
:restarts — dbg:*print-restart-frames*
:invisible — dbg:*print-invisible-frames*
```

Note that the call frames are always displayed, so there is no option to control that.

4

The REPL Inspector

LispWorks provides two inspectors. One is for use with the LispWorks IDE, and is described in the *LispWorks IDE User Guide*. The other is the REPL inspector, which uses a stream interface, and can be used on any terminal (in particular within the LispWorks IDE Listener tool). Both inspectors allow you to traverse complex data structures interactively and to destructively modify components of these structures. However, the two inspectors are quite different. No attempt has been made to make their usage compatible and instead each inspector is designed to exploit to the full the particular environment facilities available.

The REPL inspector provides a simple inspector facility which can be used on a stream providing line breaks as the only type of formatting. It is built on top of the `describe` function which is briefly described below and modifies the top level loop in a similar way to the debugger (see Chapter 3, “The Debugger”).

4.1 Describe

The function `describe` displays the slots of composite data structures in a manner dependent on the type of the object. The slots are labeled with a name where appropriate, or otherwise with a number.

The example below shows the result of calling `describe` on a simple list.

```

USER 7 > (setq countries '("Chile" "Peru" "Paraguay"
                           "Brazil"))
          ("Chile" "Peru" "Paraguay" "Brazil")

USER 8 > (describe countries)
("Chile" "Peru" "Paraguay" "Brazil") is a CONS
[0] : "Chile"

[1] : "Peru"

[2] : "Paraguay"

[3] : "Brazil"

```

`describe` describes slots recursively up to a limit set by the special variable `*describe-level*`. Note that only arrays, structures and conses are printed recursively. The slots of all other object types are only printed when at the top level of `describe`.

`*describe-level*` has an initial value of 1.

The symbols `*describe-print-level*` and `*describe-print-length*` are similar in effect to `*trace-print-level*` and `*trace-print-length*`. They control, respectively, the depth to which nested objects are printed (initial value 10), and the number of components of an object which are printed (initial value 10).

To customize `describe`, define new methods on the generic function `describe-object`.

4.2 Inspect

The function `inspect` is an interactive version of `describe`. It displays objects in a similar way to `describe`. Entering the inspector causes a new level of the top loop to be entered with a special prompt indicating that the inspector has been entered and showing the current inspector level.

In the modified top loop, if you enter a slot name, that slot is inspected and the current object is pushed onto an internal stack of previously inspected objects. The special variables `$`, `$$`, and `$$$` are bound to the top three objects on the inspector stack.

The following keywords are treated specially as commands by the inspector.

Table 4.1 Inspector commands

Command	Meaning
<code>:cv</code>	Display current values of control variables.
<code>:d</code>	Display current object.
<code>:dm</code>	Display more of current object.
<code>:dr</code>	Display rest of current object.
<code>:h</code>	Display help on inspector commands.
<code>:i m</code>	Recursively invoke a new inspector. <i>m</i> is an object to inspect.
<code>:m</code>	Change the inspection mode — see Section 4.3 on page 30.
<code>:q</code>	Quit current inspector.
<code>:s n v</code>	Sets slot <i>n</i> to value <i>v</i> .
<code>:sh</code>	Show inspector stack.
<code>:u int</code>	Undo last inspection. If you supply an optional integer argument, <i>int</i> , then the last <i>int</i> inspections are undone.
<code>:ud</code>	Undo last inspection and redisplay current object.

You can get brief help listing these commands by entering `:?` at the inspector prompt.

The control variables `*inspect-print-level*` and `*inspect-print-length*` are similar to `*describe-print-level*` and `*describe-print-length*` (see above).

`:dm` displays more slots of the current object. If the object has more than `*describe-length*` slots, then the first `*describe-length*` will be printed, followed by an ellipsis and then

`(:dm or :dr for more)`

If you enter the command `:dm` at the prompt it displays the next `*describe-length*` slots, and if you enter `:dr` it displays all the remaining slots. This

only works on the last inspected object, so if you recursively inspect a slot and come back, `:dm` does not do anything useful. Typing `:d` lets you view the object again.

`:ud` is equivalent to typing `:u` followed by `:d`.

4.3 Inspection modes

The `:m` command displays and changes the current inspection mode for an inspected value. The session below demonstrates how it works:

```
CL-USER 128 > (inspect "a
string with
newlines in it")

"a
string with
newlines in it" is a SIMPLE-BASE-STRING
0      #\a
1      #\Newline
2      #\s
3      #\t
4      #\r
5      #\i
6      #\n
7      #\g
8      #\Space
9      #\w
10     #\i
11     #\t
12     #\h
13     #\Newline
14     #\n
15     #\e
16     #\w
17     #\l
18     #\i
19     #\n ..... (:dm or :dr for more)

CL-USER 129 : Inspect 1 > :m
* 1. SIMPLE-STRING
  2. LINES
```

The `:m` produces an enumerated list of inspection modes for this value.

The asterisk next to

```
* 1. SIMPLE-STRING
```

means that SIMPLE-STRING is the current inspection mode.

You can change mode by typing :m followed by the name or number of another mode. To change to LINES mode:

```
CL-USER 130 : Inspect 1 > :m 2

" a
string with
newlines in it" is a SIMPLE-BASE-STRING
0      a
1      string with
2      newlines in it
```

4.3.1 Hash table inspection modes

There are five hash table inspection modes. They can be accessed in either the LispWorks IDE Inspector tool or the REPL inspector.

A brief introduction to the representation of hash tables is necessary so that you can fully understand what you gain from the new modes.

Internally, a hash table is a structure containing, among other things,

- a big vector
- size and growth information
- accessing functions.

When keys and values are added to the table, sufficiently similar keys are converted into the same index in the vector. When this happens, the similar keys and values are kept together in a chain that hangs off this place in the vector.

The different inspection modes provide views of different pieces of this structure:

HASH-TABLE	This mode is the “normal” view of a hash table; as a table of keys and values. When you inspect an item you inspect the value of the item.
-------------------	--

STRUCTURE This mode provides a raw view of the whole hash table structure. When you inspect an item you are inspecting the value of that slot in the hash table structure.

ENUMERATED-HASH-TABLE

This mode is a variation of the normal view, where a hash table is viewed simply as a list of lists. When you inspect an item you are inspecting a list containing a key and a value.

HASH-TABLE-STATISTICS

This mode shows how long the chains in the hash table are, so that you can tell how efficiently it is being used. For example, if all chains contained fewer than two items the hash table would be being used well.

HASH-TABLE-HISTOGRAM

This mode shows the statistical information from **HASH-TABLE-STATISTICS** as a histogram.

Here is an example of hash table inspection.

```
CL-USER 1 > (defvar *hash* (make-hash-table))
*HASH*

CL-USER 2 > (setf (gethash 'lisp *hash*) 'programming
                    (gethash 'java *hash*) 'programming
                    (gethash 'c *hash*) 'programming
                    (gethash 'c++ *hash*) 'programming
                    (gethash 'english *hash*) 'natural
                    (gethash 'german *hash*) 'natural)
NATURAL

CL-USER 3 > (inspect *hash*)

#<EQL Hash Table{6} 21C15D97> is a HASH-TABLE
C++      PROGRAMMING
JAVA     PROGRAMMING
ENGLISH  NATURAL
C        PROGRAMMING
GERMAN   NATURAL
LISP     PROGRAMMING

CL-USER 4 : Inspect 1 > :m
* 1. HASH-TABLE
  2. STRUCTURE
  3. ENUMERATED-HASH-TABLE
  4. HASH-TABLE-STATISTICS
  5. HASH-TABLE-HISTOGRAM
```

STRUCTURE mode displays the raw representation of the hash table:

```
CL-USER 5 : Inspect 1 > :m 2

#<EQL Hash Table{6} 21C15D97> is a HASH-TABLE
KIND                  EQL
SIZE                 37
REHASH-SIZE          2.0
REHASH-THRESHOLD    1.0
THRESHOLD            37
COUNTER              525
NUMBER-ENTRIES       6
TABLE                #(#%((LISP . PROGRAMMING) NIL) NIL NIL
NIL NIL ...)
NO-DESTRUCT-REHASH  NIL
POWER2               NIL
HASH-REM              SYSTEM::DIVIDE-GENERAL
HASH-FN               SYSTEM::EQL-HASHFN
GETHASH-FN            SYSTEM::GETHASH-EQL
PUTHASH-FN            SYSTEM::PUTHASH-EQL
REMHASH-FN            SYSTEM::REMHASH-EQL
GET-TLATTER-FN       SYSTEM::GET-TLATTER-EQL
WEAK-KIND             NIL
USER-STUFF            NIL
MODIFICATION-COUNTER 0
FAST-LOCK-SLOT        0
```

In **ENUMERATED-HASH-TABLE** mode you can recursively inspect keys and values by entering the index. This is especially useful in cases where the key or value is unreadable and so cannot be entered into the REPL:

```
CL-USER 6 : Inspect 1 > :m 3

#<EQL Hash Table{6} 21C15D97> is an Enumerated HASH TABLE
0      (C++ PROGRAMMING)
1      (JAVA PROGRAMMING)
2      (ENGLISH NATURAL)
3      (C PROGRAMMING)
4      (GERMAN NATURAL)
5      (LISP PROGRAMMING)

CL-USER 7 : Inspect 1 > 5

(LISP PROGRAMMING) is a LIST
0      LISP
1      PROGRAMMING

CL-USER 8 : Inspect 2 > :u
```

The **HASH-TABLE-STATISTICS** mode shows that ***hash*** has 31 chains, of which 25 are empty and 6 have one entry::

```
CL-USER 9 : Inspect 1 > :m 4

#<EQL Hash Table{6} 21C15D97> is a HASH-TABLE (statistical view)
chain of length 0 :          31
chain of length 1 :          6
```

In **HASH-TABLE-HISTOGRAM** mode the same information is represented as a histogram:

```
CL-USER 10 : Inspect 1 > :m 5

#<EQL Hash Table{6} 21C15D97> is a HASH-TABLE (histogram view)
chain of length 0 :          "*****"
chain of length 1 :          "*****"

CL-USER 11 : Inspect 1 > :q
#<EQL Hash Table{6} 21C15D97>
```

5

The Trace Facility

The trace facility is a debugging aid enabling you to follow the execution of particular functions. At any time there are a set of functions (and macros and methods) which are being monitored in this way. The normal behavior when a call is made to one of these functions is for the function's name, arguments and results to be printed out by the system. More generally you can specify that particular forms should be executed before or after entering a function, or that certain calls to the function should cause it to enter the main debugger. Tracing of a function continues even if the function is redefined.

The standard way of arranging for functions to be traced is to call the macro `trace` with the symbols of the functions (or macros or generic functions) concerned. In addition it is possible to restrict tracing to a particular method (rather than a generic function) as described in “Tracing methods” on page 47. The trace facility also handles recursive and nested calls to the functions concerned.

5.1 Simple tracing

This section shows you how to perform simple traces.

1. Type this definition of the factorial function `fac` into the listener:

```
(defun fac (n)
  (if (= n 1) 1
    (* n (fac (- n 1)))))
```

2. Now trace the function by typing the following into the listener.

```
(trace fac)
```

3. Call the function `fac` as follows:

```
(fac 3)
```

The following trace output appears in the listener.

```
0 FAC > (3)
 1 FAC > (2)
   2 FAC > (1)
   2 FAC < (1)
 1 FAC < (2)
0 FAC < (6)
```

Upon entry to each traced function call, `trace` prints the following information:

- The *level* of tracing, that is, the number of recursive entries to `trace` (starting at 0).
- The function name.
- The argument for the current call.

Each call is indented according to the level of tracing for the call.

Upon exit from each call, the same information is produced: The `>` symbol denotes entry to a function, and the `<` symbol denotes exit from it.

Output produced in this way is always sent to a special stream, `*trace-output*`, which is either associated with the listener, or with background output. You can give other expressions to be sent to this stream, in addition to the arguments and results of a function.

Calling `trace` with no arguments produces a list of all the functions currently being traced. In order to cease tracing a function the macro `untrace` should be called with commands. All tracing can be removed by calling `untrace` with no arguments.

```

CL-USER 5 > (untrace fac)
NIL
CL-USER 6 > (fac 4)
24

CL-USER 7 >

```

5.2 Tracing options

There are a number of options available when using the trace facilities, which allow you both to restrict or expand upon the information printed during a trace. For instance, you can restrict tracing of a function to a particular process, or specify additional actions to be taken on function call entry and exit.

Note that the options and values available only apply to a particular traced function. Each traced function has its own, independent, set of options.

This section describes the options that are available. Each option can be set as described above.

5.2.1 Evaluating forms on entry to and exit from a traced function

:before	<i>Trace keyword</i>
----------------	----------------------

:before *list of forms*

If non-nil, the list of forms is evaluated on entry to the function being traced. The forms are evaluated and the results printed after the arguments to the function.

Here is an example of its use. *traced-arglist* is bound to the list of arguments given to the function being traced. In this example, it is used to accumulate a list of all the arguments to `fac` across all iterations.

1. In the listener, initialize the variable `args-in-reverse` as follows:

```
(setq args-in-reverse ())
```

2. For the `fac` function used earlier, set the value of `:before` to the following list:

```
((push (car *traced-arglist*) args-in-reverse))
```

3. In the listener, evaluate the following form:

```
(fac 3)
```

After evaluating this form, `args-in-reverse` has the value `(1 2 3)`, that is, it lists the arguments which `fac` was called with, in the reverse order they were called in.

:after	<i>Trace keyword</i>
--------	----------------------

:after *list of forms*

If non-nil, this option evaluates a list of forms upon return from the function to be traced. The forms are evaluated and the results printed after the results of a call to the function.

This option is used in exactly the same way as `:before`. For instance, using the example for `:before` as a basis, create a list called `results-in-reverse`, and set the value of `:after` so that `(car *traced-results*)` is pushed onto this list. After calling `fac`, `results-in-reverse` contains the results returned from `fac`, in reverse order.

Note also that `*traced-arglist*` is still bound.

5.2.2 Evaluating forms without printing results

:eval-before	<i>Trace keyword</i>
--------------	----------------------

:eval-before *list-of-forms*

This option allows you to supply a list of forms for evaluation upon entering the traced function. The forms are evaluated after printing out the arguments to the function, but unlike `:before` their results are not printed.

:eval-after	<i>Trace keyword</i>
-------------	----------------------

:eval-after *list-of-forms*

This option allows you to supply a list of forms for evaluation upon leaving the traced function. The forms are evaluated after printing out

the results of the function call, but unlike `:after` their results are not printed.

5.2.3 Using the debugger when tracing

`:break`

Trace keyword

`:break form`

If *form* evaluates to non-nil, the debugger is entered directly from `trace`. If it returns `nil`, tracing continues as normal. This option lets you force entry to the debugger by supplying a *form* as simple as `t`.

Upon entry to the traced function, the standard trace information is printed, any supplied `:before` forms are executed, and then *form* is evaluated.

`:break-on-exit`

Trace keyword

`:break-on-exit form`

Like `:break`, this option allows you to enter the debugger from `trace`. It differs in that the debugger is entered *after* the function call is complete.

Upon exit from the traced function, the standard trace information is printed, and then *form* is evaluated. Finally, any supplied `:after` forms are executed.

`:backtrace`

Trace keyword

`:backtrace backtrace`

Generates a backtrace on each call to the traced function. *backtrace* can be any of the following values:

`:quick` Like the `:bq` debugger command.

`t` Like the `:b` debugger command.

`:verbose` Like the `:b :verbose` debugger command.

`:bug-form` Like the `:bug-form` debugger command.

5.2.4 Entering stepping mode

:step *Trace keyword*

:step *form*

When non-nil, this option puts the trace facility into stepper mode, where interpreted code is printed out one step of execution at a time.

5.2.5 Configuring function entry and exit information

:entrycond *Trace keyword*

:entrycond *form*

This option controls the printing of information on entry to a traced function. *form* is evaluated upon entry to the function, and information is printed if and only if *form* evaluates to t. This allows you to turn off printing of function entry information by supplying a *form* of nil, as in the example below.

:exitcond *Trace keyword*

:exitcond *form*

This option controls the printing of information on exit from a traced function. *form* is evaluated upon exit from the function, and, like :entrycond, information is printed if and only if *form* evaluates to t. This allows you to turn off printing of function exit information by supplying a *form* of nil.

An example of using :exitcond and :entrycond is shown below:

1. For the fac function, set the values of :entrycond and :exitcond as follows.

```
:entrycond  => (evenp (car *traced-arglist*))  
:exitcond   => (oddp (car *traced-arglist*))
```

Information is only printed on entry to `fac` if the argument passed to `fac` is even. Conversely, information is only printed on exit from `fac` if the argument passed to `fac` is odd.

2. Type the following call to `fac` in a listener:

```
CL-USER 12 > (fac 10)
```

The tracing information printed is as follows:

```
0 FAC > (10)
2 FAC > (8)
4 FAC > (6)
6 FAC > (4)
8 FAC > (2)
9 FAC < (1)
7 FAC < (6)
5 FAC < (120)
3 FAC < (5040)
1 FAC < (362880)
```

5.2.6 Directing trace output

`:trace-output`

Trace keyword

```
:trace-output stream
```

This option allows you to direct trace output to a stream other than the listener in which the original function call was made. By using this you can arrange to dispatch traced output from different functions to different places.

Consider the following example:

1. In the listener, create a file stream as follows:

```
CL-USER 129 > (setq str (open "trace.txt" :direction :output))
Warning: Setting unbound variable STR
#<File stream "/u/neald/trace.txt">
```

2. Set the value of the `:trace-output` option for the function `fac` to `str`.
3. Call the `fac` function, and then close the file stream as follows:

```
CL-USER 138 > (fac 8)
40320

CL-USER 139 > (close str)
T
```

Inspect the file `trace.txt` in order to see the trace output for the call of `(fac 8)`.

5.2.7 Restricting tracing

:process *Trace keyword*

:process process

This lets you restrict tracing of a function to a particular process. If *process* evaluates to `t`, then the function is traced from within all processes (this is the default). Otherwise, the function is only traced from within the process that *process* evaluates to.

:when *Trace keyword*

:when form

This lets you invoke the tracing facilities on a traced function selectively. Before each call to the function, *form* is evaluated. If *form* evaluates to `nil`, no tracing is done. The contents of `hcl:*traced-arglist*` can be examined by *form* to find the arguments given to `trace`.

5.2.8 Storing the memory allocation made during a function call

:allocation *Trace keyword*

:allocation form

If *form* is non-nil, this prints the memory allocation, in bytes, made during a function call. The symbol that *form* evaluates to is used to accumulate the amount of memory allocated between entering and exiting the traced function.

Note that this symbol continues to be used as an accumulator on subsequent calls to the traced function; the value is compounded, rather than over-written.

Consider the example below:

1. For the `fac` function, set the value of `:allocation` to `$$fac-alloc`.
2. In the listener, call `fac`, and then evaluate `$$fac-alloc`.

```
CL-USER 152 > $$fac-alloc
744
```

5.2.9 Tracing functions from inside other functions

<code>:inside</code>	<i>Trace keyword</i>
----------------------	----------------------

`:inside list-of-functions`

The functions given in the argument to `:inside` should reference the traced function in their implementation. The traced function is then only traced in calls to any function in the list of functions, rather than in direct calls to itself.

For example:

1. Define the function `fac2`, which calls `fac`, as follows:

```
(defun fac2 (x)
  (fac x))
```

2. For the `fac` function, set the value of `:inside` to `fac2`.
3. Call `fac`, and notice that no tracing information is produced.

```
CL-USER 154 > (fac 3)
6
```

4. Call `fac2`, and notice the tracing information.

```
CL-USER 155 > (fac2 3)
0 FAC > (3)
 1 FAC > (2)
   2 FAC > (1)
   2 FAC < (1)
 1 FAC < (2)
0 FAC < (6)
```

5.3 Example

The following example illustrates how `trace` may be used as a debugging tool. Suppose that you have defined a function `f`, and intend its first argument to be a non-negative number. You can trap calls to `f` where this is not true, providing an entry into the main debugger in these cases. It is then possible for you to investigate how the problem arose.

To do this, you specify a `:break` option for `f` using `trace`. If the form following this option evaluates to a non-nil value upon calling the function, then the debugger is entered. In order to inspect the first argument to the function `f`, you have access to the variable `*traced-arglist*`. This variable is bound to a list of the arguments with which the function was called, so the first member of the list corresponds to the first argument of `f` when tracing `f`.

```
CL-USER 12 > (defun f (a1 a2) (+ (sqrt a1) a2))
F

CL-USER 13 > (trace (f :break (< (car *traced-arglist*) 0)))
F

CL-USER 14 > (f 9.0 3)
0 F > (9.0 3)
0 F < (6.0)
6.0

CL-USER 15 > (f -16.0 3)
0 F > (-16.0 3)

Break on entry to F
 1 (continue) return from break.
 2 (abort) return to level 0.
 3 return to top loop level 0.
 4 Destroy process.

Type :c followed by a number to proceed
```

5.4 Tracing methods

You can also trace methods (primary and auxiliary) within a generic function. The following example shows how to specify any qualifiers and specializers.

- Type the following methods into the listener:

```
(defmethod foo (x)
  (print 'there))

(defmethod foo :before ((x integer))
  (print 'hello))
```

- Next, trace only the second of these methods by typing the following definition spec.

```
(trace (method foo :before (integer)))
```

- Test that the trace has worked by calling the methods in the listener:

```
CL-USER 226 > (foo 'x)
```

```
THERE
THERE
```

```
CL-USER 227 > (foo 4)
0 (METHOD FOO :BEFORE (INTEGER)) > (4)
```

```
HELLO
0 (METHOD FOO :BEFORE (INTEGER)) < (HELLO)
```

```
THERE
THERE
```

```
CL-USER 228 >
```

5.5 Trace variables

`hcl:*max-trace-indent*`

Variable

The maximum indentation used during output from `trace`.

hcl:trace-indent-width* *Variable*

The additional amount by which tracing output is indented upon entering a deeper level of nesting.

hcl:trace-level* *Variable*

The current depth of tracing.

cl:trace-output* *Variable*

The stream to which tracing sends its output by default.

hcl:traced-arglist* *Variable*

The variable that holds the arguments given to the traced function.

hcl:traced-results* *Variable*

The variable that holds the results from the traced function.

The following four variables allow the output produced by tracing to be printed in a style that is controlled separately from normal printing:

hcl:trace-print-circle* *Variable*

The value to which `*print-circle*` is bound during output from `trace`.

hcl:trace-print-length* *Variable*

The value to which `*print-length*` is bound during output from `trace`.

hcl:trace-print-level* *Variable*

The value to which `*print-level*` is bound during output from `trace`.

<code>hcl:*trace-print-pretty*</code>	<i>Variable</i>
---------------------------------------	-----------------

The value to which `*print-pretty*` is bound during output from `trace`.

5.6 Troubleshooting tracing

This section describes some of the common problems seen when tracing, with suggestions to overcome these.

5.6.1 Excessive output

In general it is not useful to trace `c1:length` and other base-level functions unconditionally because they are called too frequently by LispWorks itself.

It may be useful to trace these functions in a limited fashion, using the `trace` options `:inside` or `:when`.

5.6.2 Missing output

There are two common reasons for not seeing calls you expect in trace output.

5.6.2.1 Compiled code may not call the functions you expect

There are many other optimizations built-in to the LispWorks compiler, which affect code generated according to the compiler qualities in effect at compile-time. For example if the compiler was set to inline structure accessors, then tracing structure accessors in code compiled with that setting will produce no output.

While debugging, you could re-compile the code at higher safety or run it interpreted, to obtain the trace output.

5.6.2.2 `trace` works on function names, not function objects

`trace` works by tracing function names, not function objects.

Therefore tracing function objects, for example by

```
(trace #'foo)
```

will not yield any trace output. Instead you need to do

```
(trace foo)
```

Also, if the symbol `foo` is traced, then code which invokes `foo` by

```
(funcall (symbol-function 'foo) ...)
```

or equivalently

```
(funcall #'foo ...)
```

will not produce any trace output. You could try something like this instead:

```
(trace (funcall
        :when (eq (car *traced-arglist*)
                  (symbol-function 'foo))))
```

6

The Advice Facility

The advice facility provides a mechanism for altering the behavior of existing functions. As a simple application of this, you may supplement the original function definition by supplying additional actions to be performed before or after the function is called. Alternatively, you may replace the function with a new piece of code that has access to the original definition, but which is free to ignore it altogether and to process the arguments to the function and return the results from the function in any way you decide. The advice facility allows you to alter the behavior of functions in a very flexible manner, and may be used to engineer anything from a minor addition of a message, to a major modification of the interface to a function, to a complete change in the behavior of a function. This facility can be helpful when debugging, or when experimenting with new versions of functions, or when you wish to locally change some functionality without affecting the original definition.

Note: It can be dangerous to put advice on system functions or functions used at low-level by the system. In general, advising a basic Common Lisp function (that is, a simple function for manipulating simple objects such as `reverse`) is dangerous, because the implementation may use it.

6.1 Defining advice

Each change that is required should be specified using the `defadvice` macro. This defines a new body of code to be used when the function is called; this piece of code is called a piece of advice. Consider the following example:

```
(defadvice
  (capi:prompt-for-file pff-1 :before)
  (message &key &allow-other-keys)
  (format t "~&Prompting for file with message ~S~%" message))
```

Here `defadvice` is given a description of the function you want to alter, a name for the piece of advice, and the keyword `:before` to indicate that you want the code carried out before `capi:prompt-for-file` is called. The rest of the call to `defadvice` specifies the additional behavior required, and consists of the lambda list for the new piece of advice and its body (the lambda list may specify keyword parameters and so forth). The advice facility arranges that `pff-1` is invoked whenever `capi:prompt-for-file` is called, and that directly after this the original definition of `capi:prompt-for-file` is called.

After executing this advice definition, demonstrate it by selecting the menu command **File > Open** in the LispWorks IDE. The message appears in the **Output** tab.

Pieces of advice may be given to be executed after the call by specifying `:after` instead of `:before` in the call to `defadvice`. So if you wished to add further code to be performed after `capi:prompt-for-file` you could also define:

```
(defadvice
  (capi:prompt-for-file pff-2 :after)
  (message &rest args)
  (format t
    "~&The other arguments to prompt-for-file were: ~S~%" args))
```

Note that `pff-2` also receives the arguments to `capi:prompt-for-file`, which are reported by the body.

6.2 Combining the advice

We have already seen how a before and an after piece of advice may be combined, and this section describes the general algorithm. There are three types of advice: *before*, *after* and *around*. These resemble before, after and around methods in CLOS. There may be several pieces of each type of advice present for a particular function.

The first step in working out how the combination is done is to order the pieces of advice. All the around advice comes first, then all the before advice, then the original definition, and lastly the after advice. The order within each of the around, before and after sections defaults to the order in which the pieces of advice were defined (that is most recent first). See `defadvice`, page 717 for details of how to control the ordering of advice within each section.

The remainder of this section discusses what happens when a function that has advice is called.

6.2.1 :before and :after advice

First we deal with the case when there is no around advice present. Here each of the pieces of before advice are called in turn, with the same arguments that were given to the function, next the original definition is called with these arguments, and finally each of the pieces of after advice is called in reverse order with the same arguments (so that by default the most recently added piece of after advice is invoked last). The results returned by the function call are the values produced by the last piece of after advice to be called (if there is one), or by the original definition (if there is no after advice).

Note that none of these bits of code should destructively modify the arguments that they receive. Adding a piece of before advice thus provides a simple way of specifying some additional action to be performed before the original definition, and before any older bits of before advice. Adding a piece of after advice allows you to specify extra actions to be performed after the original definition, and after any older bits of after advice. The advice facility automatically links together these bits of advice with the original function definition.

6.2.2 :around advice

Next we shall discuss the use of around advice, which provides you with greater control than do before and after advice. Let us suppose that a function that has some around advice is called. The arguments to the function are passed to the code associated with the first piece of around advice in the ordering, and the values returned by that piece of advice are the results of the function. There is no requirement for the advice to invoke any other pieces of advice, nor to call the original definition of the function.

However the code for any piece of around advice has access to the next member of the ordering, which it may invoke any number of times by calling `call-next-advice`. So it is possible for each piece of around advice to call its successor in the ordering if this is desired, and then the bits of around advice are called in turn in a similar fashion to our earlier description for before and after advice. However in the case of around advice the decision whether or not to call the next piece of advice is directly under your control, and you are free to modify the arguments received by the piece of advice, and to choose the arguments to be given to the next piece of advice if it is called.

If the last piece of around advice in the ordering calls `call-next-advice`, then it invokes the combination of before and after advice and the original definition that was discussed earlier. That is, the arguments to the call are given in the sequence described above to each of the before pieces of advice, then to the original definition and then to the after pieces of advice. The call to `call-next-advice` returns with the values produced by the last of these subsidiary calls, and the around advice may use these values in any way.

6.3 Removing advice

The macro `delete-advice` (or the function `remove-advice`) may be used to remove a named piece of advice. Since several pieces of advice may be attached to a single functional definition, the name must be supplied to indicate which one is to be removed.

```
CL-USER 40 > (delete-advice capi:prompt-for-file pff-1)
NIL
```

```
CL-USER 41 > (delete-advice capi:prompt-for-file pff-2)
NIL
```

6.4 Advice for macros and methods

As well as attaching advice to ordinary functions, it may also be attached to macros and methods.

In the case of a macro, advice is linked to the macro's expansion function, and so any before or after advice receives a copy of the arguments given to this expansion function (normally the macro call form and an environment). A simple example:

```
CL-USER 45 > (defmacro twice (b) `(+ ,b ,b))
TWICE

CL-USER 46 > (defadvice
  (twice before-twice :before)
  (call-form env)
  (format t
    "~~Twice with environment ~A and call-form ~A"
    env call-form))
NIL

CL-USER 47 > (twice 3)
Twice with environment NIL and call-form (TWICE 3)
6
```

Note that the advice is invoked when the macro's expansion function is used. So if the macro is present within a function that is being compiled, then the advice is invoked during compilation of that function (and not when that function is finally used).

In the case of a method, the call to `defadvice` must also specify precisely to which method the advice belongs. A generic function may have several methods, so the call to `defadvice` includes a list of classes. This must correspond exactly to the parameter specializers of one of the methods for that generic function, and it is to that method that the advice is attached. For example:

```

CL-USER 45 > (progn
  (defclass animal ()
    (genus habitat description
      (food-type :accessor eats)
      (happiness :accessor how-happy)
      (eaten :accessor eaten :initform nil)))
  (defclass cat (animal)
    ((food-type :initform 'fish)))
  (defclass elephant (animal)
    (memory (food-type :initform 'hay)))
  (defmethod feed ((animal animal))
    (let ((food (eats animal)))
      (push food (eaten animal))
      (format t "~%Feeding ~A with ~A" animal
        food)))
  (defmethod feed ((animal cat))
    (let ((food (eats animal)))
      (push food (eaten animal))
      (push 'milk (eaten animal))
      (format t "~%Feeding cat ~A with ~A and ~A"
        animal food 'milk)))
  (defvar *cat* (make-instance 'cat))
  (defvar *nellie* (make-instance 'elephant)))
*PELLIE*

CL-USER 46 > (feed *cat*)
Feeding cat #<CAT 6f35d4> with FISH and MILK
NIL

CL-USER 47 > (feed *nellie*)
Feeding #<ELEPHANT 71e7bc> with HAY
NIL

CL-USER 48 > (defadvice
  ((method feed (animal))
   after-feed :after)
  (animal)
  (format t "~%-A has eaten ~A"
    animal (eaten animal)))
NIL
CL-USER 49 > (defadvice
  ((method feed (cat))
   before-feed :before)
  (animal)
  (format t "~%Stroking ~A" animal)
  (setf (how-happy animal) 'high))
NIL

```

```

CL-USER 50 > (feed *cat*)
Stroking #<CAT 6f35d4>
Feeding cat #<CAT 6f35d4> with FISH and MILK
NIL

CL-USER 51 > (feed *nellie*)
Feeding #<ELEPHANT 71eb7c> with HAY
#<ELEPHANT 71eb7c> has eaten (HAY HAY)

```

6.5 Examples

So far you have only seen examples of before and after pieces of advice. This section contains some further examples. Suppose that you define a function `alpha` that squares a number, and then decide that you intended to return the reciprocal of the square instead. You might proceed as follows.

```

CL-USER 30 > (defun alpha (x) (* x x))
ALPHA

CL-USER 31 > (defadvice
                 (alpha reciprocal :around)
                 (num)
                 (/ (call-next-advice num)))
NIL

CL-USER 32 > (alpha -5)
1/25

```

First you change `alpha` to return the reciprocal of the square. Do this by defining an around method to take the reciprocal of the result produced by the next piece of advice (which initially is the original definition). Now suppose that you later decide that you would like `alpha` to return the sum of the squares of the reciprocals in a certain range. You can achieve this by adding an extra layer of around advice. This must iterate over the range required, summing the results obtained by the calls to the next piece of advice (which currently yields the reciprocal of the square of its argument).

```
CL-USER 36 > (defadvice
                  (alpha sum-over-range :around)
                  (start end)
                  (loop for i from start upto end
                        summing (call-next-advice i)))
NIL

CL-USER 37 > (alpha 2 5)
1669/3600
```

Note that `alpha` now behaves as a function requiring two arguments; the outer piece of around advice determines the external interface to the function, and uses the inner pieces of advice as it needs - in this case invoking the inner advice a variable number of times depending on the range specified. The use of the words “outer” and “inner” corresponds to earlier and later pieces of around advice in the ordering discussed above, but is more descriptive of their behavior.

You now realize that taking the reciprocal of zero gives an error. You decide that you wish to generate an error if `alpha` is called in such a way as to cause this, but that you want to generate the error yourself. You also decide to add a warning message for negative arguments. As you want these actions to be performed as the last (that is innermost) in the chain of around advice, you specify this in the call to `defadvice` by giving it a `:where` keyword with value `:end`.

```

CL-USER 41 > (defadvice
    (alpha zero-or-negative
        :around :where :end)
    (x)
    (unless (plusp x)
        (format t
            "~%**Warning: alpha is being called with ~A"
            x))
    (if (zerop x)
        (error "Alpha cannot be called with zero")
        (call-next-advice x)))
NIL

CL-USER 42 > (alpha -5 -2)

**Warning: alpha is being called with -5
**Warning: alpha is being called with -4
**Warning: alpha is being called with -3
**Warning: alpha is being called with -2
1669/3600

CL-USER 43 > (alpha 0 3)

**Warning: alpha is being called with 0
Error: alpha cannot be called with zero
  1 (abort) return to level 0.
  2 return to top loop level 0

Type :c followed by a number to proceed

CL-USER 44 : 1 > :a

```

Finally you decide to alter `alpha` yet again, this time to produce approximations to π . $\pi^2/6$ is the sum of the reciprocals of the squares of all the positive integers. So you can generate an approximation to π using the sum of the reciprocals of the squares of the integers from one to some limit. (In fact this is not an efficient way of calculating π , but it could be of interest.)

```

CL-USER 51 > (defadvice
    (alpha pi-approximation :around)
    (limit)
    (sqrt
        (* 6
            (call-next-advice 1.0 limit))))
NIL

```

Next, try calling the following in turn:

```
(alpha 10.0)
(alpha 100.0)
(alpha 1000.0)
pi
```

Lastly, here is a simple example showing a use of advice with an `&rest` lambda list:

```
(defun foo (a b c)
  (print (list a b c)))

(defadvice (foo and-rest-advice :around) (&rest args)
  (format t "advice called with args ~S" args)
  (apply #'call-next-advice args))
```

6.6 Advice functions and macros

The main functions used for advice are introduced below. See the reference pages for full details.

The main macro used to define new pieces of advice is `defadvice`

Pieces of around advice should use `call-next-advice` to invoke the next piece of advice. As explained earlier this either calls the next piece of around advice (if one exists), or calls the combination of before advice, the original definition, and after advice. It may only be called from within the body of the around advice.

To remove a piece of advice, use the macro `delete-advice` or the function `remove-advice`.

Dspecs: Tools for Handling Definitions

The dspec system is the machinery underlying the way definitions are named in LispWorks. It supports program development by tracking the locations of definitions, and is also used in tracing and advising functions.

Dspecs are not expected to work in runtimes delivered at a delivery level greater than 0.

This chapter explains the concepts underlying dspecs and their use in tracking locations of definitions. For full details of the programming interface, see Chapter 30, “The DSPEC Package”.

7.1 Dspecs

Definition specifications, or *dspecs*, are a systematic way of naming definitions. The dspec system includes all kinds of definitions provided in LispWorks, and can be extended to include definers that you add.

Most named definitions are global, but local functions can have names, and some of the operations described here can be applied to them as well.

Here are three examples of dspecs:

```
car  
(setf car)
```

```
(defclass standard-object)
```

A dspec is simply a name: you can operate on it even if the thing named does not currently exist.

7.2 Forms of dspecs

A dspec is one of:

- A symbol
- A `setf` function name
- A list starting with a symbol naming the class of definition (`method` or `defstruct` for example).

A symbol which is used as a dspec always names a function or a macro.

`(setf foo)` is a name for a `setf` function.

Note: `nil` is not a legal dspec, because it cannot have a function definition. Therefore when a dspec API returns `nil`, this should be interpreted in the usual way as "not found" or "not applicable".

7.2.1 Canonical dspecs

Internally, dspecs are handled in the canonical form:

```
(dspec-class primary-name . qualifiers)
```

where *dspec-class* is the canonical name of the class, and *qualifiers* is a proper list. *primary-name* is typically a symbol, but can be a list (in the case of a `setf` function) or a string (in the case of a package). The equality for canonical dspecs is `equal`.

As an example the general form of a `defmethod` dspec is:

```
(defmethod name qualifiers (specializer*))
```

name	:	=	symbol	 	(setf symbol)
qualifiers	:	=	qualifier	 	(qualifier qualifier*)
qualifier	:	=	symbol		
specializer	:	=	symbol	 	(eql object)

Functions in the dspec API accept non-canonical dspecs. All dspec functions, except `dspec:prettify-dspec`, `find-dspec-locations`, `name-definition-locations`, `dspec-definition-locations` and `find-name-locations` return canonical dspecs.

7.3 Dspec namespaces

Dspec classes are the namespaces for dspecs. Class names are often the same as the name of the defining form, though documentation types as defined for `documentation` are also used. See “Details of system dspec classes and aliases” on page 68 for a list of the classes.

7.3.1 Dspec classes

Dspec classes provide a set of handlers, to allow uniform handling of different types of definitions by other parts of the system, such as the editor and various browsers.

The most important handlers are `dspec-defined-p` and `dspec-undefiner` for testing if a dspec is currently defined and for undefining a dspec.

New dspec classes are defined using `define-dspec-class`.

Dspec classes can be subclassed. The top-level classes correspond to distinct global namespaces (such as `variable` for variables and constants and `function` for functions and macros), and at each level, all the subclasses are distinct from each other (but they do not have to form a complete partition of the superclass). See “Details of system dspec classes and aliases” on page 68 for the full hierarchy of system-provided classes.

You are allowed to define new top-level classes and subclass them, but you cannot add new subclasses to a system-provided class. However, see “Dspec aliases” on page 66 for how to add new ways of making existing definitions.

7.3.1.1 Complete example of a top-level dspec class

Define a `saved-value` object which has a name and a value:

```
(defstruct saved-value
  name
  value)
```

The objects are defined using `def-saved-value` and stored on the plist of their name:

```
(defmacro def-saved-value (name value)
  `(dspec:def (def-saved-value ,name)
    (when (record-definition `(def-saved-value ',name)
                               (dspec:location))
      (setf (get ',name 'saved-value)
            (make-saved-value :name ',name
                              :value ,value)))
    ',name)))
```

Define a function to retrieve the `saved-value` object:

```
(defun find-saved-value (name)
  (get name 'saved-value))
```

Define a macro to access a `saved-value` object:

```
(defmacro saved-value (name)
  `(saved-value-value (find-saved-value ',name)))
```

Define a dspec class for `def-saved-value` dspecs:

```
(dspec:define-dspec-class def-saved-value nil
  "Defined saved values"
  :definedp
  #'(lambda (name)
      ;; Find any object that def-saved-value recorded
      (not (null (find-saved-value name))))
  :undefinedp
  #'(lambda (dspec)
      ;; Remove what def-saved-value recorded
      `(remprop ,(dspec:dspec-name dspec) 'saved-value))
  :object-dspec
  #'(lambda (obj)
      ;; Given a saved-value object, we can reconstruct its dspec
      (and (saved-value-p obj)
           `(def-saved-value ,(saved-value-name obj)))))
```

For completeness, define a form parser that generates dspecs from forms:

```
(dspec:define-form-parser
  (def-saved-value
    (:parser dspec:single-form-form-parser)))
```

Note: this form parser for `def-saved-value` is not strictly necessary, because the system provides an implicit form parser which recognizes definitions beginning with "def".

7.3.1.2 Example of subclassing

This example is based on that in “Complete example of a top-level dspec class” on page 63.

Define a `computed-saved-value` object has a function to compute the value the first time:

```
(defstruct (computed-saved-value (:include saved-value))
  function)
```

`saved-value` objects are defined using `def-computed-saved-value` and stored on the plist of their name:

```
(defmacro def-computed-saved-value (name function)
  `(dspec:def (def-computed-saved-value ,name)
    (when (record-definition `,(def-computed-saved-value ',name)
      ,(dspec:location))
      (setf (get ',name 'saved-value)
        (make-computed-saved-value :name ',name
          :function ,function)))
    ',name)))
```

Define a function to compute a `computed-saved-value`:

```
(defun ensure-saved-value-computed (name)
  (let ((saved-value (find-saved-value name)))
    (or (saved-value-value saved-value)
        (setf (saved-value-value saved-value)
          (funcall
            (computed-saved-value-function saved-value))))))
```

Define a macro to access a `computed-saved-value`:

```
(defmacro computed-saved-value (name)
  `(ensure-saved-value-computed ',name))
```

Define a dspec class for `def-computed-saved-value` dspecs:

```
(dspec:define-dspec-class def-computed-saved-value def-saved-
value
  "Defined computed saved values"
  :definedp
  #'(lambda (name)
    ;; Find any object that def-computed-saved-value recorded
    (computed-saved-value-p (find-saved-value name)))
  ;; The :undefiner is inherited from the superspace.
  :object-dspec
  #'(lambda (obj)
    ;; Given a computed-saved-value object, we can reconstruct
    its dspec
    (and (computed-saved-value-p obj)
         `(def-computed-saved-value ,(saved-value-name obj)))))
```

For completeness, define a form parser that generates dspecs from forms:

```
(dspec:define-form-parser
  (def-computed-saved-value
    (:parser dspec:single-form-form-parser)))
```

Note: this form parser for `def-computed-saved-value` is not strictly necessary, because the implicit form parser will recognize definitions beginning with "def".

7.3.2 Dspec aliases

You can add new ways of making existing definitions and use the dspec system to track these definitions. This is what happens when your defining form expands into a system-provided form. The macro `define-dspec-alias` is used to inform the dspec system of this.

For example if your definer is:

```
(defmacro my-defun ((name &rest args) &body body)
  `(defun ,name ,args ,@body))
```

then you would define the form of dspecs for `my-defun` definitions like this:

```
(dspec:define-dspec-alias my-defun (name)
  `(defun ,name))
```

Note: in general you should not include the lambda list in the dspec, because it is not needed to locate the definition later.

Note: to make source location work you will also need a `define-form-parser` definition for `my-defun`. This is illustrated in “Using pre-defined form parsers” on page 74.

7.4 Types of relations between definitions

7.4.1 Functionally equivalent definers

When one definition form simply macroexpands into another, or otherwise has an identical effect as far as the dspec system is concerned, the dspec system should consider them variant forms of the same class.

Use `define-dspec-alias` to convert one definer to the other during canonicalization. A pre-defined example of this in LispWorks is `defparameter` and `defvar`. These cannot be distinguished (other than in the source code), so `defparameter` has been defined as a dspec alias for `defvar`. However, `defvar` and `defconstant` are distinct kinds of variable, since we can easily tell which type of definition is in effect by calling the function `constantp`. To define their dspecs, LispWorks creates a dspec class called `variable` and uses it as the superspace argument when defining the `defvar` and `defconstant` dspec classes.

As an explicit example, suppose you have a defining macro

```
(defmacro parameterdef (value name)
  `(defparameter ,name ,value))
```

then

```
(dspec:define-dspec-alias parameterdef (value name)
  `(defparameter ,name))
```

would be a suitable appropriate alias definition. This `define-dspec-alias` form defines the dspec.

`define-dspec-alias` is like `defmacro` for dspecs, so it could be used to describe complicated conversions, as long as it can be done purely statically and totally in terms of existing dspecs. However, nothing more complicated than `defparameter` has been found necessary.

7.4.2 Grouping subdefinitions together

Some definition forms are macros that expand into a group of other definitions, for example `defstruct`. When the form is associated with a dspec class, the subdefinitions can be automatically recorded as being subforms of the new definition, by use of the `def` macro.

This means that the dspec system knows that the subdefinitions were inside the main definition (indeed, inside this particular form). Therefore

- Location queries can retrieve this information.
- The source location commands in the LispWorks IDE, when passed a subdefinition, know to search for the main definition given in the `def`.

Note: to make source location work you will also need a `define-form-parser` definition for the macro that expands into the `def`.

Note: `def` defines a relation between two particular definitions, for example `(defstruct foo)` and `(defun make-foo)`, not between the two dspec classes.

7.4.3 Distributed definitions

Some definitions are additions to another class of definition, for example methods are additions to generic functions. We call these *distributed definitions*, consisting of "parts" and "the aggregate".

The primary name of a part gives the primary name of the aggregate it is a part of, and the qualifiers distinguish it from the other parts of the same aggregate. Only a part dspec may have qualifiers.

7.5 Details of system dspec classes and aliases

This section shows the dspec classes, subclasses and aliases provided by the system. Subclasses are indented. Following the list of dspec classes are notes about some of these classes.

The system-defined dspec classes are:

```

COMPILER-MACRO (alias DEFINE-COMPILER-MACRO)
EDITOR:DEFCOMMAND (alias EDITOR:DEFINE-COMMAND-SYNONYM)
DEFINE-ACTION
DEFINE-ACTION-LIST
WIN32:DEFINE-DDE-CLIENT
WIN32:DEFINE-DDE-DISPATCH-TOPIC
DSPEC:DEFINE-DSPEC-CLASS (aliases DSPEC:DEFINE-SUBCLASS-DSPEC-CLASS,
DSPEC:DEFINE-FUNCTION-DSPEC-CLASS)
DSPEC:DEFINE-DSPEC-ALIAS
EDITOR:DEFINE-EDITOR-VARIABLE (alias EDITOR:DEFINE-EDITOR-MODE-VARIABLE)
FLI:DEFINE-FOREIGN-CALLABLE
FLI:DEFINE-FOREIGN-TYPE (alias FLI:DEFINE-FOREIGN-CONVERTER)
DSPEC:DEFINE-FORM-PARSER
CAPI:DEFINE-MENU
DEFSETF (aliases DEFINE-SETF-EXPANDER, DEFINE-SETF-METHOD)
DEFSYSTEM
FUNCTION
  DEFGENERIC
  DEFMACRO (alias DEFINE-MODIFY-MACRO)
  DEFUN (alias SYSTEM:DEFUN-AND-INLINE)
    FLI:DEFINE-FOREIGN-VARIABLE
    FLI:DEFINE-FOREIGN-FUNCTION (alias FLI:DEFINE-FOREIGN-FUNCALLABLE)
  METHOD (alias DEFMETHOD)
  METHOD-COMBINATION (alias DEFINE-METHOD-COMBINATION)
  PACKAGE (alias DEFPACKAGE)
  STRUCTURE (alias DEFSTRUCT)
TYPE
  DEFCLASS
    CAPI:DEFINE-INTERFACE
    CAPI:DEFINE-LAYOUT
    DEFINE-CONDITION
    STRUCTURE-CLASS
  DEFTYPE
VARIABLE
  DEFINE-SYMBOL-MACRO
  DEFCONSTANT
  DEFVAR (aliases DEFGLOBAL-PARAMETER, DEFGLOBAL-VARIABLE,
  DEFPARAMETER)

```

Further dspec classes are defined by modules such as `com` (on Microsoft Windows), `kw` and `sql`.

The canonical form of a symbol dspec is (`function symbol`) and the canonical form of a setf function name dspec is (`function (setf symbol)`).

7.5.1 CLOS dspec classes

`defgeneric` and `method` can handle `standard-generic-function` and `standard-method`.

7.5.2 Part Classes

`method` is a part class for `defgeneric`.

`compiler-macro` is a part class for `function`.

7.5.3 Foreign callable dspecs

For `fli:define-foreign-callable` the canonical name is the foreign name, with any machine-specific prefixes omitted.

7.6 Subfunction dspecs

For some purposes, we allow dspecs that do not name a global definition, but a local function. These are of the form

`(subfunction name parent)`

where *parent* is another dspec (possibly even a `subfunction` dspec).

name is a symbol, a list, or a number, but it is not used for anything within the dspec system. A `subfunction` dspec can be canonicalized and prettified, and passed as an argument to `dspec-definition-locations` (which will find where *parent* is defined).

Additionally pseudo-dspecs like this are allowed for top-level forms:

`(top-level-form (location <#>))`

location is a basic location and *<#>* identifies the top-level form within that location. These are used as parent dspecs in `subfunction` dspecs and `:inside` locations. These dspecs can be canonicalized and prettified, and can be returned as dspecs from the location finders.

7.7 Tracking definitions

The dspec system is used to keep track of global definitions in many ways, and global definition macros usually tell the dspec system when the definition changes.

The main purpose of the system is to keep track of where the definition was located, but it also allows fine-tuned control of redefinitions.

7.7.1 Locations

Locations are mainly something the dspec system just stores and retrieves. :inside locations are used to describe definitions located as subforms of other definitions.

:inside locations are usually not explicitly specified, but arise as a result of having two nested definitions, both of which use the `def` and `location` macros to handle the name and location info.

The types of locations and their meanings are:

A pathname A definition existed in the file named or an editor buffer with that name.

The keyword :listener

A definition was executed interactively in the listener or an editor buffer not associated with a file.

The keyword :unknown

A definition was found in the image (these are entered when a location query does not find any information already in the database).

The keyword :implicit

A definition for a part was recorded, but no information exists for the aggregate.

7.7.2 Recording definitions and redefinition checking

The location information is entered into the database when the definition is executed, by the defining function calling `record-definition`.

`record-definition` performs various checks, and returns true or false depending on whether the definition was allowed or not. In particular, it checks if the same name has already been defined in a different location and if so a warning or error can be signalled. See `record-definition`, page 536 for details.

7.7.2.1 Use of record-definition

You should not usually call `record-definition`, since all the system-provided definers call it.

However, for new classes of definition which you add with `define-dspec-class`, you should call `record-definition` for dspecs in their new classes, as shown in “Complete example of a top-level dspec class” on page 63.

7.8 Finding locations

There are two ways of retrieving location information for definitions in the running LispWorks image:

- query for a dspec using `dspec-definition-locations`, or
- query for a name in a given set of namespaces using `name-definition-locations`

The difference is that name queries will find the locations of all the part definitions as well as the definition named, whereas dspec queries will only find the locations for the definition named (there might be many if it has been redefined).

To provide for sub-definitions hidden in another definition, such as `defstruct` accessors, all location queries produce a list of pairs of dspecs and locations, each pair naming a definition within the corresponding location that contains the definition looked for. So a query for an accessor called `foobar` might produce the pair:

```
(defstruct foo) #P"/usr/users/hacker/hacks/hack.lisp")
```

7.9 Users of location information

To find location information for definitions made in the running image or recorded in a tags database or a tags file:

- query for a *dspec* using `find-dspec-locations`, or
- query for a *name* in a given set of namespaces using `find-name-locations`

The extent of the search is controlled by the value of the variable `*active-finders*`.

For example, to obtain the locations of the definitions of `foo` across all *dspec* namespaces, call

```
(dspec:find-name-locations dspec:*dspec-classes* 'foo)
```

Another example of the use of `find-name-locations` is the LispWorks Editor tool's Find Definitions tab.

7.9.1 Finding definitions in the LispWorks editor

Returning to our example `parameterdef` definer

```
(defmacro parameterdef (value name)
  `(defparameter ,name ,value))
```

1. Load a file `foo.lisp` containing
`(parameterdef 42 *foo*)`
2. Now use **Expression > Find Source** on the symbol `*foo*`. Notice that LispWorks knows which file the definition is in, but cannot find the defining top level form.
3. Also notice that the Definitions tab of the Editor tool does not display the definition of `*foo*`. This is because the Editor does not recognise `parameterdef` as a definer. When the LispWorks editor looks at the definitions in a buffer, it needs to know the *dspecs* that each defining form will generate when evaluated. You can tell the editor how to parse a defining form to generate the *dSpec* by using `define-form-parser`.

4. Now evaluate these forms to associate a parser with `parameterdef` and inform the dspec system that `parameterdef` is another way of naming a `defparameter` dspec:

```
(dspec:define-form-parser parameterdef (value name)
  `(parameterdef ,name))
```

```
(dspec:define-dspec-alias parameterdef (name)
  `(defparameter ,name))
```

5. Now use **Expression > Find Source** on the symbol `*foo*` again. Notice that the source of the definition of `*foo*` is displayed correctly in the text tab of the Editor tool, and that the Definitions tab displays the definition as

```
(parameterdef *foo*)
```

7.9.2 Using pre-defined form parsers

LispWorks provides form parsers `name-only-form-parser`, `single-form-form-parser` and `single-form-with-options-form-parser`. You can use `single-form-with-options-form-parser` as the parser for `my-defun` definitions (see “Dspec aliases” on page 66), like this:

```
(dspec:define-form-parser (my-defun
  (:parser dspec:single-form-with-options-form-parser)))
```

This allows the Editor to locate definitions like:

```
(my-defun (foo x y)
  (+ x y))
```

You can identify the form parser defined for a dspec class using `get-form-parser`.

7.9.3 The editor’s implicit form parser

When testing your form parsers bear in mind that the LispWorks editor has an implicit form parser, independent of explicit parsers defined in the dspec system. It tries to parse a dspec from a top level form which is of length 2 or more and whose car has symbol name beginning with "DEF". That is:

```
(defxyz name forms)
```

gets parsed as

```
(defxyz name)
```

which may be a dspec (and thus provides a match for the source location commands). This mechanism operates only when there's no explicit parser defined for `defxyz`.

The editor's implicit form parser is useful because it matches a common simple case. However it does not work for the `parameterdef` example, because that definer's symbol name does not begin with "DEF".

7.9.4 Reusing form parsers

The form parser established above was specifically for `parameterdef` forms. However if you have other definers of similar syntax - in this example, definers for which the name is the second subform - then you can define a form parser which can be associated with each of them, as follows:

```
(dspec:define-form-parser (name-second (:anonymous t))
  (value name)
  ` (,name-second ,name))
```

Note that the `name-second` variable is evaluated in the body of the parser. Supposing you have another defining macro `constantdef`:

```
(defmacro constantdef (value name)
  ` (defconstant ,name ,value))
```

then you can associate the same parser with both this and `parameterdef`:

```
(dspec:define-form-parser (parameterdef
  (:parser name-second-form-parser)))
(dspeс:define-form-parser (constantdef
  (:parser name-second-form-parser)))
```

7.9.5 Example: defcondition

Suppose you have a macro based on `define-condition`:

```
(defmacro defcondition (&rest args)
  ` (define-condition ,@args))
```

When the following form is evaluated, the system records the dspec (define-condition foo):

```
(defcondition foo () ())
```

Two setups are needed to allow the editor to locate such a defining form.

Firstly, this tells the system how to parse (defcondition ...) toplevel forms:

```
(dspec:define-form-parser
  (defcondition
    (:alias define-condition)))
```

So now:

```
(dspec:parse-form-dspec '(defcondition foo () ()))
=>
(defcondition foo)
```

Secondly, this tells the system that (defcondition foo) is an alias for (define-condition foo).

With this, the editor would report "Cannot find (DEFINE-CONDITION FOO) in ...".

```
(dspec:define-dspec-alias defcondition (name)
  `(define-condition ,name))
```

So now this definition can be located:

```
(defcondition foo () ())
```

just as if it were:

```
(define-condition foo () ())
```

7.9.6 Example: my-defmethod

Suppose you have a method definer `my-defmethod`:

```
(defmacro my-defmethod ((name &key doc)
                        lambda-list
                        &body body)
  ` (defmethod ,name ,lambda-list ,@body))
```

Unlike function dspecs, method dspecs need to include the specialized argument types as well as the function name, so the alias and the parser both need to be more complex.

This causes the dspec to include the argument types:

```
(dspec:define-dspec-alias my-defmethod (name &rest options)
  ` (defmethod ,name ,@options))
```

The dspec parser for method lambda lists is complicated, but you can invoke the `defmethod` parser in your `my-defmethod` parser, like this:

```
(dspec:define-form-parser my-defmethod (name-stuff lambda-list)
  ` (,my-defmethod ,@(cdr (dspec:parse-form-dspec
    ` (defmethod ,(car name-stuff)
      ,lambda-list))))
```

Now this definition can be located:

```
(my-defmethod (bar :doc "bar documentation") (x y)
  (foo x y))
```

just as if it were:

```
(defmethod bar (x y)
  (foo x y))
```

8

Action Lists

Action-lists are a unified approach to various different mechanisms for running initializations, or “hook” functions at various points during the life of the system. They provide central gathering points for applications to trigger on system-wide events such as start-up, disk-save, and so on.

An action-list is a tagged list of data, to be executed (in some sense) in sequence whenever the circumstance identified by its tag occurs. It is expected that whatever code detects or causes the circumstance will take care of running the action-list.

An execution-function can be specified for the action-list when it is created. Otherwise, the default behavior is to treat the data of each action as a callable and apply it to any additional arguments specified at execution time. At its simplest, an action-list emulates (`map nil 'funcall`).

Names of action-lists and action-items are general lisp objects, compared with `equalp`. This allows strings and other objects to be used as unique identifiers.

Actions can be specified to depend on other actions; when defining an action-item, you can say that it must be before or after other action-items using the `:before` and `:after` keywords. Aside from that, actions are assumed to have no dependencies, and no order of execution should be counted on for the actions in a list.

You can (and are encouraged to) specify a documentation string for action-lists or action-items.

In addition you can create action-lists that are not registered globally. This allows applications to have disembodied action lists for their own internal purposes. The other action-list functions allow an action-list to be passed in instead of a name, to accommodate this.

8.1 Defining action lists and actions

Action lists are defined using the `define-action-list` macro, and are undefined using the `undefine-action-list`. It is also possible to make unnamed, unregistered lists using `make-unregistered-action-list`.

When defining an action-list, the user may provide an associated execution-function. When executing the action-list, this user-defined execution-function is used instead of the default execution-function, to map over and “execute” the action-list's action-items. The macro `with-action-list-mapping` provides facilities to map over action-items (that is, their corresponding “data”). In addition, the macro `with-action-list-mapping` provides a simple mechanism to trap errors and print warnings while executing each action-item.

Actions are added to an action list using `define-action`, and are removed using `undefine-action`.

8.2 Exception handling variables

Three global variables control the handling of exceptions in action list and action item operations.

The variable `*handle-existing-action-list*` controls the behavior of `define-action-list` when the action list already exists. It allows you to control independently both:

- whether you are notified, and
- whether the action list gets redefined

The variable `*handle-existing-action-in-action-list*` controls the behavior of `define-action` when the action already exists in the given action-list. It allows you to control independently both:

- whether you are notified, and
- whether the action item gets redefined

The variable `*handle-missing-action-list*` specifies behavior when one of `undefine-action-list`, `print-actions`, `execute-actions`, `define-action` and `undefine-action` is called on a missing action-list. By default, an error is signalled, but you can make it warn or ignore instead.

The variable `*handle-missing-action-in-action-list*` specifies behavior when you attempt to undefine a missing action. By default, a warning is signalled, but you can make it signal error, or ignore, instead.

8.3 Other variables

The variable `*default-action-list-sort-time*` specifies when actions in action-lists are sorted. By default actions are sorted at the time of execution of the action list, but you can cause them to be sorted at action definition time instead.

See `define-action-list` for an explanation of ordering specifiers.

8.4 Diagnostic utilities

Two diagnostic functions are provided:

- `print-actions` prints out the actions on a specified action list
- `print-action-lists` prints a list of all the defined action lists

8.5 Examples

This example illustrates “typical” use of action lists. The `define-action` forms might be scattered across several files (`mail-utilities.lisp`, `caf-define.lisp`, and so on). Each of the functions, such as `read-mail`, `dont-panic`, and so on, take one argument: `hassled-p`.

```
(in-package "CL-USER")
```

```

(define-action-list "On arrival at office"
  :documentation "Things to do in the morning"
  :dummy-actions '("Look busy")
  :default-order '(:before "Look busy"))

(define-action "On arrival at office" "Read mail" 'read-mail)

(define-action "On arrival at office" "Greet co-workers"
  'say-hello)

(define-action "On arrival at office" "Drink much coffee"
  'wake-up:after "Locate coffee machine")

(define-action "On arrival at office" "Locate coffee machine"
  'dont-panic)

(defun my-morning (hassled-p Monday-p)
  (execute-actions ("On arrival at office"
    :ignore-errors-p Monday-p)
    hassled-p)
  <rest of my-morning code goes here>
)

```

This example illustrates use of execution-functions and post-processing

```
(in-package "CL-USER")
```

Here are the implementation details, which are hidden from the “user”.

```

(defstruct (thing (:constructor make-thing (name number)))
  name
  number)

(defvar *things*
  (make-unregistered-action-list :sort-time :define-action
    :execution-function 'act-on-things))

(defun do-things (function &optional post-process)
  (execute-actions (*things* :post-process post-process)
    function))

(defun act-on-things (things other-args-list &key post-process)
  (with-action-list-mapping
    (things ignore thing post-process)
    (destructuring-bind
      (function) other-args-list
      (funcall function thing))))

```

The interface is given below. The internals of the mapping mechanism are hidden.

```
(defmacro define-thing (name number)
  (with-unique-names (thing)
    `(let ((,thing (make-thing ,name ,number)))
       (define-action *things* ',name ,thing)))))

(defmacro undefine-thing (name)
  `(~(undefined-action *things* ,name) ,))

(defun find-thing (name)
  (do-things #'(lambda (thing)
                  (and (equal name (thing-name thing))
                       thing))
              :or))

(defun add-things ()
  (reduce '+ (do-things 'thing-number :collect)))
```

8.6 Standard Action Lists

The following action lists are defined in LispWorks as shipped:

"When starting image" - Actions to be executed upon image startup.

"Confirm when quitting image" - Actions to be executed before the image quits. Every action must return non-nil as its first value, otherwise the quit will be aborted once the actions are complete.

"When quitting image" - Actions to be executed when the image quits, after success of the "Confirm when quitting image" actions.

"Initialize LispWorks Tools" - Things to do when the LispWorks IDE starts on a screen. You may customise your environment startup by defining actions on it.

"Delivery Actions" - Actions to be executed when doing delivery. Actions on this list are executed in a 'normal' environment. See the *Delivery User Guide* for an example action item.

"Save Session Before" - Actions executed before saving a session. See `save-current-session` for details.

"Save Session After" - Actions executed after saving a session and redisplaying all the windows. These actions are executed both in the saving image and in the saved image when restarted. See `save-current-session` for details.

9

The Compiler

The compiler translates Lisp forms and source files into binary code for the host machine. A compiled Lisp function, for instance, is a sequence of machine instructions that directly execute the actions the evaluator would perform in interpreting an application of the original source lambda expression. Where possible the behaviors of compiled and interpreted versions of the same Lisp function are identical. Unfortunately the definition of the Common Lisp language results in certain unavoidable exceptions to this rule. The compiler, for instance, must macroexpand the source before translating it; any side effects of macro-expansion happen only once, at compile time.

By using declarations, you can advise the compiler of the types of variables local to a function or shared across an application. For example, numeric operations on a variable declared as a `single-float` can be compiled as direct floating-point operations, without the need to check the type at execution time. You can also control the relative emphasis the compiler places on efficiency (speed and space), safety (type checking) and support for debugging. By default the compiler produces code that performs all the necessary type checking and includes code to recover from errors. It is especially important that the type declarations be correct when compiling with a safety level less than 3 (see later in this chapter for more details).

When compiling a Lisp source file, the compiler produces its output in a format that is much faster to load than textual Lisp source — the “fasl” or “fast-

load” form. Fasl files contain arbitrary Common Lisp objects in a pre-digested form. They are loaded without needing to use the expensive `read` function. A series of “fasl-loader” routines built into LispWorks interpret the contents of fasl files, building the appropriate objects and structures in such a way that objects that were `eq` before fasl-dumping are created `eq` when fasl-loaded.

Fasl files are given pathname extensions that reflect the target processor they were compiled for; as the fasl files contain processor specific instruction sequences it is essential that the loader be able to distinguish between files compiled for different targets. These pathname extensions always end in “fasl”. See `compile-file` for details of all the possible fasl file extensions.

9.1 Compiling a function

The function `compile` takes a symbol as its first argument, and an interpreted function definition (a lambda expression) as its second, optional, argument. It compiles the definition and installs the resultant code as the symbol-function of the symbol (unless the symbol was `nil`). If the definition is omitted then the current symbol-function of the symbol is used. Below are some examples:

```
CL-USER 3 > (compile (defun fred (a b)
                               (dotimes (n a) (funcall b))))
; FRED
FRED
NIL
NIL

CL-USER 4 > (funcall (compile nil '(lambda (n)
                                         (* n n))) 7)
; NIL
49

CL-USER 5 > (compile 'ident-fun '(lambda (x) x))
; IDENT-FUN
IDENT-FUN
NIL
NIL
```

9.2 Compiling a source file

The function `compile-file` takes a pathname as its argument and compiles all the forms in the file, producing a corresponding fasl file (with pathname derived from the source pathname). Any side effects in the source file are only felt once the compiled file is subsequently loaded. Many proclamations, for example, are not visible at compile time. The special form `eval-when` can be used to force such side effects to take effect at the time of compilation, rather than loading.

9.3 Compiling a form

To compile an arbitrary form *form* (as opposed to a function), call

```
(compile form)
```

This compiles *form* as if by `compile-file` but without any file related processing and does it in-memory, so it has also the same effect as loading. This has a similar effect to compiling a definition in the LispWorks Editor tool, except that there is no source recording.

Using `compile` this way is especially useful if you need to dynamically define something that is normally defined by a top level or, for example `kw: defrule`.

9.4 How the compiler works

Conceptually the compiler can be viewed as performing a series of separate passes.

- In the first pass the source code is macro expanded in the appropriate macro environment.
- A series of source to source optimizing transformations are performed to simplify the source tree. Type declarations are used to select specialized, efficient versions of low level functions.
- A graph is generated from the source tree. The structure of the graph reflects the flow of control in the tree. The nodes of the graph contain blocks of intermediate code for an abstract machine with byte addressing and an infinite set of registers. Register allocation is performed

based on data flow analysis and machine specific rules concerning live ranges across code fragments.

- The blocks of intermediate code are translated into a single linear sequence of target machine code through a process of template matching.
- Finally the relative branch instructions are “fixed up” to point to the correct locations in the code sequence.

The compiler is in fact much more complex than this model might suggest. Machine specific optimizations, for example, can be included in any of the passes. The distinction between passes is also not as simple as that listed above. However, this description is sufficient to allow the programmer to make optimal use of the compiler.

9.5 Compiler control

There are ways to control the nature of compiled code via the `declare` special form and `proclaim` function. See later in this chapter for fuller discussion of these two forms.

In particular there are a set of optimize qualities which take integral values from 0 to 3, in order to control the trade-offs between code size, speed, compilation time, debuggability of the resulting code, and the safety of the code (whether type checks are omitted). For example:

```
(proclaim '(optimize (speed 3) (safety 0) (debug 0)))
```

tells the compiler to concentrate on code speed rather than anything else, and

```
(proclaim '(optimize (safety 3)))
```

ensures that the compiler never takes liberties with Lisp semantics and produces code that checks for every kind of signallable error.

The important declarations to the compiler are type declarations and optimize declarations. To declare that the type of the value of a variable can be relied upon to be unchanging (and hence allow the compiler to omit various checks in the code), say:

```
(declare (type the-type variable * ))
```

Optimize declarations have various qualities, and these take values from 0 to 3. The names are `safety`, `fixnum-safety`, `float`, `sys:interruptable`, `debug`, `speed`, `compilation-speed`, and `space`.

Most of the qualities default to 1 (but `safety` and `fixnum-safety` default to 3 and `interruptable` defaults to 0). You can either associate an optimize quality with a new value (with local lexical scope if in `declare`, and global scope if `proclaim`), or just give it by itself, which implies the value 3 (taken to mean “maximum” in some loose sense).

Thus you ensure code is at maximum safety by:

```
(proclaim '(optimize (safety 3)))
```

or

```
(proclaim '(optimize safety))
```

and reduce debugging information to a minimum by

```
(proclaim '(optimize (debug 0)))
```

Normally code is interruptible, but when going for the extreme levels of speed and “undebuggability” this ceases to be the case unless you also ensure it thus:

```
(proclaim '(optimize (debug 0) (safety 0) (speed 3)
                     interruptable))
```

The levels of `safety` have the following implications:

- 0 implies no type checking upon reading or writing from defstructs, arrays and objects in general, nor any checking of array index bounds.
- 1 implies no type checking upon reading from defstructs, arrays and objects in general, nor any checking of array index bounds when reading. However, array index bounds are checked when writing.
- 2 implies type checking when writing, but not when reading. Other than this the compiler generates generally safe code, but allows `type` and `fixnum-safety` declarations to take effect. Array index bounds are checked for both reading and writing.
- 3 (default) implies complete type and bounds checking, and disallows `fixnum-safety` and `type` declarations from taking any effect.

The levels of `fixnum-safety` have the following implications:

- 0 implies no type checking of arguments to numeric operations, which are assumed to be fixnums. Also the result is assumed, without checking, to not overflow - this level means single machine instructions can be generated for most common integer operations, but risks generating values that may confuse the garbage collector.
- 1 implies that numeric operations do not check their argument types (assumed fixnum), but do signal an error if the result would have been out of range.
- 2 implies that numeric operations signal an error if their arguments are non-fixnum, and also check for overflow.
- 3 (default) implies complete conformance to the semantics of Common Lisp numbers, so that types other than integers are handled in compiled code.

Additionally if the level of `float` (really this should be called “float-safety”) is 0 then the compiler reduces allocation during float calculations.

The effects of combining these qualities is summarized below:

Table 9.1 Combining debug and safety levels in the compiler

Keyword settings	Operations
<code>safety=0</code>	Array access optimizations
<code>debug>0</code>	Dumps symbol names for arglist
<code>debug>=2</code>	Ensure debugger knows values of args (and variable when source debugging is on)
<code>debug<1</code>	Does not generate any debug info at all
<code>debug=3</code>	Avoids <code>make-instance</code> and <code>find-class</code> optimizations
<code>debug=3</code>	Avoids <code>gethash</code> and <code>puthash</code> optimizations
<code>debug=3</code>	Avoids <code>ldb</code> and <code>dpb</code> optimizations
<code>debug=3</code>	Avoids an optimization to <code>last</code>

Table 9.1 Combining debug and safety levels in the compiler

Keyword settings	Operations
<code>safety>1</code>	Be careful when multiple value counts are wrong
<code>safety<1</code>	Do not check array indices during write
<code>safety<2</code>	Do not check array indices during read
<code>speed>space</code>	Inline map functions (unless <code>debug>2</code>)
<code>debug<=2</code>	Optimize (merge) tail calls
<code>debug<2 and safety<2</code>	Self calls
<code>safety>=2</code>	Check get special
<code>safety<2</code>	Do not check types during write
<code>safety<3</code>	Do not check types during read
<code>safety>=1</code>	Check structure access
<code>safety<=1</code>	Inline structure readers, with no type check
<code>safety=0</code>	Inline structure writers, with no type check
<code>safety>1</code>	Check number of args
<code>safety>=1 or interruptible>0</code>	Check stack overflow
<code>safety>1</code>	Ensures the thing being funcalled is a function
<code>safety<3 and fixnum-safety=2</code>	Fixnum-only arithmetic with errors for non fixnum arguments.
<code>safety<3 and fixnum-safety=1</code>	No fixnum overflow checks
<code>safety<3 and fixnum-safety=0</code>	No fixnum arithmetic checks at all
<code>safety>2</code>	<code>char=</code> checks for arguments of type <code>character</code>
<code>safety>=2</code>	Ensures symbols in <code>progv</code>
<code>debug=3</code>	Avoids “ad hoc” predicate type transforms

Table 9.1 Combining debug and safety levels in the compiler

Keyword settings	Operations
<code>compilation-speed=3</code>	Reuse virtual registers in very large functions
<code>debug=3 and safety=3</code>	(<code>declare (type foo x)</code>) and (<code>the foo x</code>) ensure a type check
<code>float=0</code>	Optimize floating point calculations

The other optimize qualities are: `speed` — the attention to fast code, `space` — the degree of compactness, `compilation-speed` — speed of compilation, `interruptable` — whether code must be interruptible when unsafe.

Note that if you compile code with a low level of safety, you may get segmentation violations if the code is incorrect (for example, if type checking is turned off and you supply incorrect types). You can check this by interpreting the code rather than compiling it.

9.5.1 Examples of compiler control

The following function, compiled with safety = 2, does not check the type of its argument because it merely reads:

```
(defun foo (x)
  (declare (optimize (safety 2)))
  (car x))
```

However the following function, also compiled with safety = 2, does check the type of its argument because it writes:

```
(defun set-foo (x y)
  (declare (optimize (safety 2)))
  (setf (car x) y))
```

As another example, interpreted code and code compiled at at low safety does not check type declarations. To make LispWorks check declarations, you need to compile your code after doing:

```
(declaim (optimize (safety 3) (debug 3)))
```

This last example shows how to copy efficiently bytes from a typed-aref vector (see `make-typed-aref-vector`) to an (`unsigned-byte 8`) array. `type` and `safety` declarations cause the compiler to inline the code that deals specifically with (`unsigned-byte 8`). This code was developed after an application was found to have a bottleneck in the original version of this function:

```
(defun copy-typed-aref-vector-to-byte-vector
  (byte-vector typed-vector length)
  (declare (optimize (safety 0))
           (type (simple-array (unsigned-byte 8) 1) byte-vector)
           (fixnum length))
  (dotimes (index length)
    (declare (type fixnum index))
    (setf (aref byte-vector index)
          (sys:typed-aref '(unsigned-byte 8)
                          typed-vector index))))
```

9.6 Declare, proclaim, and declaim

The special form `declare` is used to:

- declare Lisp variables as “special”, which affects the semantics of the appropriate bindings of the variables, or
- help the system (in reality the compiler) run your Lisp code faster, or
- make the code run with more sophisticated debugging options, or
- help you optimize your code

`declare` behaves computationally as if it is not present (other than to affect the semantics), and is only allowed in certain contexts, such as after the variable list in a `let`, `do`, `defun` and so on. Consult the syntax definition of each special form to see if it accepts `declare` forms.

For the details, including some LispWorks extensions to Common Lisp, see the reference entry for `declare`.

The function `proclaim` parses declarations in a specified list and then puts their semantics and advice into global effect. This can be useful when compiling a file for speedy execution, since a proclamation such as:

```
(proclaim '(optimize (speed 3) (space 0) (debug 0)))
```

causes the rest of the file to be compiled with these optimization levels in effect. (A lengthier way to do this is to make appropriate declarations in every function in the file.) Below are some more examples:

```
(proclaim '(special *fred*))  
(proclaim '(type single-float x y z))  
(proclaim '(optimize (safety 0) (speed 3)))
```

Do not forget to quote the argument list if it is a constant list. This form:

```
(proclaim (special x))
```

attempts to call function `special`.

`declaim` is a macro equivalent to `proclaim`.

9.6.1 Naming conventions

Exercise caution if you `declare` or `proclaim` variables to be special without regard to the naming convention that surrounds their names with asterisks.

9.7 Optimizing your code

Careful use of the compiler optimize qualities described above or special declarations may significantly improve the performance of your code. However it is not recommended that you simply experiment with the effect of adding declarations. It is more productive to work systematically:

1. Use the Profiler, described in Chapter 11, “The Profiler”, to analyse your application’s performance and identify bottlenecks, then
2. Consider whether re-writing of parts of your source code would improve efficiency at the bottlenecks, and
3. Use `:explain` declarations to make the compiler generate optimization hints, and
4. (In SMP LispWorks) use `analysing-special-variables-usage` to report on symbols proclaimed special, and
5. Consider adding suitable declarations as described in this chapter to improve efficiency at the bottlenecks.

The most important tool for speeding up programs is the Profiler. You use the profiler to find the bottlenecks in the program, and then optimize these bottlenecks by helping the compiler to produce better code.

The remainder of this section describes some specific ways to produce efficient compiled code with LispWorks.

9.7.1 Compiler optimization hints

You can make the compiler print messages which will help you to optimize your code. You add suitable `:explain` declarations, recompile the code, and check the output.

The full syntax of the `:explain` declaration is documented in the reference entry for `declare`.

Various keywords allows you to see information about compiler transformations depending on type information, allocation of floats and bignums, floating point variables, function calls, argument types and so on. Here is a simple example:

```
(defun foo (arg)
  (declare (:explain :variables) (optimize (float 0)))
  (let* ((double-arg (coerce arg 'double-float))
         (next (+ double-arg 1d0))
         (other (* double-arg 1/2)))
    (values next other)))
;;- Variables with non-floating point types:
;;- ARG OTHER
;;- Variables with floating point types:
;;- DOUBLE-ARG NEXT
```

Note: the LispWorks IDE allows you to distinguish compiler optimization hints from the other output of compilation, and also helps you to locate quickly the source of each hint. For more information see the chapter “The Output Browser” in the *LispWorks IDE User Guide*.

9.7.2 Fast 32-bit arithmetic

The INT32 API provides a way to perform optimal raw 32-bit arithmetic. Note that, unlike Lisp integer types, this is modulo 2^{32} like the C int type.

The INT32 symbols are all in the system package.

The Lisp type `int32` reads 32 bits of memory, like `(signed-byte 32)`, but the data is in `int32` format for use with the INT32 API.

9.7.2.1 Optimized and unoptimized INT32 code

When optimized correctly, the intermediate `int32` objects are not constructed.

In unoptimized code, sequences of operations like

```
(sys:int32+ (sys:int32- a b) (sys:int32- c d))
```

will generate intermediate `int32` objects for the results of the subtraction, but the compiler can optimize these away because it knows that the function `int32+` consumes `int32` objects.

Note: the INT32 API is not designed to optimize `sys:int32` objects passed as arguments.

9.7.2.2 The INT32 API

The INT32 API contains the type `int32`, a vector type `simple-int32-vector` and accessor, functions to convert `int32` to and from integer, some constant `int32` values, and a full range of operators for mod 2^{32} arithmetic.

You can find all these by evaluating

```
(apropos "INT32" "SYSTEM" t)
```

For details for each, see the entries starting with `int32` in Chapter 40, “The SYSTEM Package”.

9.7.2.3 INT32 Optimization

The optimization works safely but without boxing when possible. You need

```
(optimize (float 0))
```

to get the optimization. This `float` level affects whether INT32 operations are optimized. This declaration must be placed at the start of a function (not on an inner `let` or `locally` form).

In this example the `safety` level assures a second optimization in `fli:foreign-typed-aref`:

```
(defun incf-signed-byte-32 (ptr index)
  (declare (optimize (safety 0) (float 0))
           (type fixnum index))
  (setf (fli:foreign-typed-aref 'sys:int32 ptr index)
        (sys:int32-1+ (fli:foreign-typed-aref 'sys:int32
                                              ptr index)))
  ;; return ptr, since otherwise the int32 would
  ;; need to be boxed to return it
  ptr)
```

9.7.3 Floating point optimization

The declaration `float` allows generation of more efficient code using float numbers. It reduces allocation during float calculations. It is best used with safety 0. That is, you declare `(optimize (float 0) (safety 0))` as in this example:

```
(progn
  (setf a
        (make-array 1000
                   :initial-element 1D0
                   :element-type 'double-float))
  nil ; to avoid printing the large array
  )

(compile
  (defun test (a)
    (declare (optimize (speed 3) (safety 0) (float 0)))
    (declare (type (simple-array double-float (1000))
                  a))
    (let ((sum 0D0))
      (declare (type double-float sum))
      (dotimes (i 1000)
        (incf sum (the double-float (aref a i)))))
      sum))

  (time (test a))
=>
Timing the evaluation of (TEST A)

user time      =      0.000
system time    =      0.000
Elapsed time   =  0:00:00
Allocation     = 16 bytes standard / 0 bytes conses
0 Page faults
```

Note: In some cases, the operations cannot be fully optimized with `float 0`, which can cause the compiled code to be larger because the unboxing and boxing of floats will be inline.

9.7.4 Tail call optimization

In 64-bit LispWorks and on x86 platforms the compiler optimizes tail calls unless

1. The compiler optimize quality `debug` is 3, or
2. There is something with dynamic scope on the stack, such as a special binding, a catch or `dynamic-extent` allocation (so it is not really a tail call)

On all other platforms the compiler optimizes tail calls unless 1.) or 2.) above apply, or

3. The call has more than 4 arguments and this is more than the number of fixed (not `&optional`/`&rest`/`&key`) parameters in the calling function.
4. The call has more than 4 arguments and the calling function has `&rest`/`&key` parameters.

9.7.5 Usage of special variables

The declaration `c1:special` specifies that a variable is special, that is it does not have lexical scope. This covers two cases: if the variable is bound in the dynamic environment (for example by `let` or `let*`), then the value of that binding is used; otherwise the value in the global environment is used, if any. An error is signaled in safe code if there is no value in either environment.

When `setq` is used with a variable, the value in the dynamic environment is modified if the variable is bound in the dynamic environment, otherwise the value in the global environment is modified. Dynamic variables can have a different value in each thread because each thread has its own dynamic environment. The global environment is shared between all threads.

In SMP LispWorks access to special variables (excluding constants) is a little slower than in non-SMP LispWorks. It can be speeded up by declarations of the symbol, normally by using `proclaim` or `declare`.

The speedup will be pretty small overall in most cases, because access to specials is usually a small part of a program. However, if the Profiler identifies some piece of code as a bottleneck, you will want to optimize it, and your optimizations may include proclamation of some variable as global or dynamic.

The three declarations described in this section are extensions to Common Lisp. All declare the symbol to be `c1:special`, along with other information. These three declarations are mutually exclusive between themselves and `c1:special`. That is, declaring a symbol with any of these declarations eliminates the other declaration:

- `hcl:special-global` declares that the symbol is never bound in the dynamic environment.

In SMP LispWorks the compiler signals error if it detects that a symbol declared as `hcl:special-global` will be bound in the dynamic environment, and at runtime it also signals an error.

In non-SMP LispWorks the compiler gives an error, but there is no runtime check. The runtime behavior is the same as `c1:special`, with all accesses to the symbol in low safety.

`hcl:special-global` is very useful, and because of the checks it is reasonably safe. It is useful not only for speed, but also to guard against unintentionally binding variables that should not be bound.

See also `defglobal-parameter`.

- `hcl:special-dynamic` declares that the symbol is always bound in the dynamic environment when it is accessed.

In high safety code accessing the symbol when it is not bound in the dynamic environment signals an error. In low safety code it may result in unpredictable behavior.

In non-SMP LispWorks the only effect of this declaration is to make all access to the variable low safety.

`hcl:special-dynamic` is useful, but because it can lead to unpredictable behavior you need to ensure that you test your program in high safety when you use it.

- `hcl:special-fast-access` declares that a symbol should be "fast access".

The semantics of the declaration is the same as `cl:special`, except that access to the variable is low safety. In addition, the compiler compiles access to the symbol in a way that speeds up the access, but also introduces a tiny reduction in the speed of the whole system. The balance between these effects is not obvious.

It is not obvious where `hcl:special-fast-access` is useful. If you can ensure that the symbol is always bound or never bound then `hcl:special-dynamic` or `hcl:special-global` are certainly better.

9.7.5.1 Finding symbols to declare

The macro `analysing-special-variables-usage` can be used to find symbols that may be proclaimed global, which can improve performance. `analysing-special-variables-usage` also helps to identify inconsistencies in the code.

9.7.5.2 Coalesce multiple special bindings

If a set of specials are always bound at the same time, it is better to store the values in a single structure object and bind one special variable to that object, to reduce the overall number of special bindings.

9.7.6 Stack allocation of objects with dynamic extent

`(declare dynamic-extent)` will optimize these calls so that they allocate in the stack, in all cases:

- `&rest` lists
- `flet` functions and `labels` functions
- `(cons x y)`
- `(list ...)`
- `(list* ...)`
- `(copy-list x)`

- `(make-list x)`
- `(vector ...)`

`(declare dynamic-extent)` will also optimize these specific calls:

- `(make-array n)`
- `(make-array n :initial-element x)` without any other arguments
- `(make-foo ...)` where `make-foo` is an inline structure constructor.
The default constructor is declared inline automatically when none of the `defstruct` slot initforms are calls to functions.
- `(make-string n :element-type 'base-char)`

9.7.7 Inlining foreign slot access

Given a structure definition

```
(fli:define-c-struct foo-struct
  (a :int)
  (b :int))
```

you can inline access to a slot by declaring `fli:foreign-slot-value` inline and supplying the *object-type*:

```
(defun foo-a (struct)
  (declare (inline fli:foreign-slot-value))
  (fli:foreign-slot-value struct 'a :object-type 'foo-struct))
```

9.8 Compiler parameters affecting LispWorks

There are six compiler parameters that control the generation of information used by various LispWorks utilities, such as the debugger, and also by various editor commands, such as `Show Paths From`. By default, these parameters are all `t`, which allows you to use all the features of these utilities, at the expense of increasing compilation times.

These variables are initially set to `t` (in the LispWorks file `config/a-dot-lispworks.lisp`). To speed up compilation times, you should set these variables to `nil`. The variables can be controlled as a group by using the function `toggle-source-debugging`.

10

Storage Management

This chapter introduces some basic ideas of storage management, and then discusses the LispWorks storage management system in more detail. The chapter also introduces the functions and macros needed to control storage management. Full details of all the symbols mentioned here are given in Chapter 32, “The HCL Package” and Chapter 40, “The SYSTEM Package”.

10.1 Introduction

Automatic memory management is one of the most significant features of a Lisp system. Whenever an object, such as a cons cell, is required to hold an aggregate of values, the system calls the appropriate function to create a new object and fill it with the intended values. The programmer need not be concerned with the low level allocation and management of memory as the Lisp system provides this functionality automatically.

When an object is no longer required (that is, it has become “garbage”), the system must automatically reclaim (“collect”) the space it occupies and reallocate the space to a new object. Whenever the space for new objects is exhausted, a “garbage collector” (GC) is run to determine (by a process of elimination) all the existing objects that are still required by the running program. Any other objects still in the image are necessarily garbage, and the space they occupy can be reclaimed.

For a description of how LispWorks uses the address space of different Operating Systems, and factors affecting the maximum image size, see “Address Space and Image Size” on page 313.

Garbage collection with a naive algorithm is extremely inefficient.

The LispWorks GC works in unison with the storage allocator to arrange allocated objects in a series of “generations”. Each generation contains objects of a particular age. In practice most Lisp data objects are only required for a very short period of time. That is, they are ephemeral. The LispWorks GC concentrates its efforts on repeatedly scanning the most recent generation. Such a scan requires only a fraction of a second and reclaims most of the space allocated since the last collection. Any object in the most recent generation that survives a number of such collections is promoted to the next youngest generation. Eventually this older generation becomes full, and only then is it collected. The generations are numbered from 0 upwards, so that generation 0 is the youngest.

The remainder of this chapter describes the LispWorks GC in more detail. The implementation and the programmatic interface differ between 32-bit and 64-bit LispWorks.

10.2 Guidance for control of the storage management system

10.2.1 General guidance

The storage management is designed with the intention that the programmer will have to do very little or nothing about it. In general, we believe that the design is quite successful, and in most cases you do not have to do anything. The main exception to this is dealing with long-lived data in long-lived processes in 32-bit LispWorks.

Before doing anything about storage management, you should be familiar with the function `room`, and use it frequently. There is no point at all in trying to tune the storage management without knowing the sizes of your application, as output by `room`.

The data and code in the LispWorks image can be categorized according to how long they live, as follows:

1. Permanent data
2. Long-lived data
3. Short-lived data

Note that the distinction is not in the data itself, but in the existence of pointers to it.

In general, you rarely need to worry about short-lived data, and have to worry about permanent data only if you have a large amount of it. In short-lived applications you do not need to worry about long-lived data either, so there is a good chance that you do not have to worry about storage management at all.

In long-lived applications, you certainly need to consider long-lived data in 32-bit LispWorks, and maybe in 64-bit LispWorks.

10.2.2 Permanent data

Permanently-living data will typically be the actual code of the application, and maybe also data that never goes away.

Because the data never goes away, it is best to put it outside normal garbage collection, which means promoting it to the highest generation. You do this by using `clean-down`.

There are several things that need to be considered when using `clean-down`:

1. Saving an image (whether by `save-image` or `deliver`) calls `clean-down` (by default), so there is no need to worry about data in a saved image.
2. If the permanent data is only a small amount compared to the long-lived data, it is not obvious that `clean-down` is needed, specially if you use a saved (or delivered) image where the code and maybe some data was already promoted.
3. `clean-down` promotes all the data that is live (that is, pointed to from some other live object) in the image when it is called. If the image contains data that is live, but later becomes garbage, it will be promoted and hence not collected until another call to `clean-down`, which will make

the image unnecessarily larger. Since this data is not being accessed, the effect on performance is small, but if there is a lot of it the effect may be significant.

4. `clean-down` needs extra memory to operate, especially in 64-bit LispWorks. For very large 64-bit LispWorks images `clean-down` may fail due to running out of swap memory.
5. `clean-down` takes a significant amount of time. If it does not cause paging, it should take seconds, but if it needs to page it may take much longer. You therefore should avoid calling it when you need the application to respond reasonably quickly.

10.2.3 Long-lived data

Long-lived data is data that lives long enough to be promoted to the highest generation to which promotion occurs automatically (the "blocking generation"), but later becomes garbage. The blocking generation is 2 in 32-bit LispWorks and (by default) 3 in 64-bit LispWorks.

You can check which generation individual objects are in (by `generation-number`), but normally you want to know the total amount of data in various generations. The function `room` is used for that. In general, it is useful to call

`(room)`

and sometimes also

`(room t)`

periodically (every 5 minutes) and log the output. In servers, such logs are essential. From this output you can see how the sizes of the various generations change over time.

If the output shows that the blocking generation grows too much, even though permanent data is not added, you will need to do something about it. In 64-bit LispWorks there is a good chance that you do not have to do anything. In 32-bit LispWorks long-lived processes (for example servers) probably need to do something.

The main thing you will do is calling `(gc-generation t)`. This garbage collects the blocking generation. You should check the state of the memory after

calling it by calling `room` again. If the amount of allocated data (as opposed to total size) did not reduce, you may have a memory leak that causes accumulation of permanent data that does not die.

If `gc-generation` does free data (that is, the allocation reduces significantly), you probably need to add calls to it to your application.

Compatibility note: In 32-bit LispWorks version 5.1 and earlier, the documented way to collect generation 2 is to call `(mark-and-sweep 2)`. `(gc-generation t)` does what `(mark-and-sweep 2)` does, plus some additional operations that improve the performance of allocation. It also has the advantage that it is the same call that is used in 64-bit LispWorks. We recommend always using `gc-generation`.

To decide when to call `gc-generation`, you need to consider the following:

1. You need to prevent excessive growth of the process.
2. You want to avoid calling `gc-generation` when the application needs to respond quickly.
3. The call will be more effective if it is done between chunks of work than in the middle of a chunk of work.

We now discuss these considerations in detail:

1. You can follow the overall size of the process by looking at the output of `(room nil)`, or programmatically by using the result of `room-values`. The definition of "excessive growth" depends on the machine that you are running on and what the server actually does. Normally you want to avoid the need for paging, so you should try to keep the size of the image below the size of real memory that it can use. For 32-bit LispWorks on modern machines that have a lot of memory, the limit will be the amount of address space the machine has. In addition, garbage collecting a larger image takes more time. In a typical 32-bit application, 100-200Mb would be the target, though it can be larger. In a 64-bit application the limit is the size of the real memory.
2. `(gc-generation t)` can take a significant amount of time. 32-bit LispWorks on a modern machine can collect 100-200Mb in less than a second if it does not page. If it pages, or has a slower CPU, it takes more time. The 64-bit GC is generally faster and better, as long as it does not page,

but since you normally deal with much more data in 64-bit images, there may be significant delays in 64-bit LispWorks. If such delays are a problem for your application, you should try to call `gc-generation` at times when it is less of a problem. Use `time` to find out how long `gc-generation` takes in various situations.

3. If you can identify places where there are no active chunks of work, you can try to place calls to `gc-generation` in these places. For servers, this is likely to be much less important than the two considerations above, but for an application that computes results using large amounts of data, this may be a significant consideration.

In 32-bit LispWorks, by default, generation 2 (which is the "blocking generation") is not collected automatically, because such collection may take a significant amount of time, so most programmers need to control when it actually happens. You can change this by using `collect-generation-2`, but usually you need better control, and do a collection of generation 2 when it is appropriate. Therefore if your application generates long-lived data, you need to add calls to `gc-generation`.

Even if you find that your application does not generate long-lived data (that is, generation 2 does not grow), it is probably a good idea to keep checking, in case some circumstances do cause it to generate long-lived data.

In 64-bit LispWorks by default generation 3 (the "blocking generation") is collected automatically, so there is a good chance that you do not have to do anything. However, you may want to call `gc-generation` explicitly when you know it is a good time to do it. You may also want to block automatic calls if they take too long: use `set-blocking-gen-num` to do that. If generation 3 becomes very big (Gigabytes), you may also consider using `marking-gc` instead of `gc-generation`.

Once you set up `gc-generation` calls, you may still see the image growing even though the allocation does not grow that much. That is normally the result of fragmentation. On 32-bit LispWorks you can use `check-fragmentation` to check for fragmentation, and `try-move-in-generation` to prevent it if needed. See "Controlling Fragmentation" on page 115 for a discussion.

In 64-bit LispWorks you have a problem with fragmentation only if you use `marking-gc`. `marking-gc` has keyword arguments that can be used to reduce

fragmentation, and there is a good chance that using these will be enough to avoid serious fragmentation. `gc-generation` can be used occasionally to eliminate all fragmentation. Check for fragmentation by using `gen-num-segments-fragmentation-state`.

10.2.4 Short-lived data

Normally you should not do anything about handling of short-lived data, because the default settings are good enough for almost all situations. Sometimes you may hit a situation where the settings are not good ("pathological case"). However, it would normally require a deep understanding of the storage system to deal with such a situation, and we will in general consider this as a bug and try to fix it. Therefore if you find such situation you should report it to Lisp Support, following the guidelines at www.lispworks.com/support/bug-report.html.

Problems with short-lived data normally just reduce the performance of some part of your application. Normally the best solution is to optimize the code to do less work, including allocating less.

To do that, first find the bottlenecks in your application by using `profile` (and `start-profiling` and `stop-profiling`). `time` and `extended-time` can then be used to determine how long specific operations take, how much they allocate and, for long operations, how long they spend in garbage collection. Based on this information you can then decide what to try to optimize.

10.3 Memory Management in 32-bit LispWorks

This section describes the garbage collector (GC) in 32-bit LispWorks 6.1.

In LispWorks for UNIX and LispWorks for Macintosh, the implementation is not significantly different to that in LispWorks 4.x or LispWorks 5.x.

In LispWorks for Windows and LispWorks for Linux, the implementation has changed since LispWorks 4.x and you may notice performance improvements relative to those versions.

10.3.1 Generations

In memory, a generation consists of a chain of segments. Each segment is a contiguous block of memory, beginning with a header and followed by the allocation area.

The first generation normally consists of two segments: the first segment is relatively small, and is where most of the allocation takes place. The second segment is called the big-chunk area, and is used for allocating large objects and when overflow occurs (see below for a discussion of overflow).

The second generation (generation 1) is an intermediate generation, for objects that have been promoted from generation 0 (typically for objects that live for some minutes).

Long-lived objects are eventually promoted to generation 2. Note that generation 2 is not scanned automatically. Therefore these objects will not be reclaimed (even if they are not referenced) until an explicit call to a GC function (for example `mark-and-sweep` on generation 2, or `clean-down`) or when the image is saved. Normally, objects are not promoted from generation 2 to generation 3, except when the image is saved.

Generation 3 normally contains only objects that existed at startup time, that is those were saved in the image. Normally it is not scanned at all, except when an image is saved.

Note that the division between the generations is a result of the promotion mechanism, and is not a property of a piece of code itself. A piece of system software code that is loaded in the system (for example, a patch) is treated the same as any other code. The garbage collection code is explicitly loaded in the static area using the function `switch-static-allocation`.

10.3.2 Allocation of objects

Normal allocation is done from a buffer, called the small objects buffer. The GC maintains a pointer to the beginning and end of the buffer, and allocates from it by moving one of the boundaries. When the buffer becomes too small the GC finds another free block and makes that the buffer.

In non-SMP LispWorks there is only one global small objects buffer. In SMP LispWorks, each process may have its own "local" small objects buffer (in

addition to the global one). The system decides dynamically which process should have a local buffer and which not. In general processes that do any significant amount of work have a local buffer, and most of their allocation would be from local buffers.

The minimum and maximum size of free block that the GC uses for the small objects buffer can be set by `set-gc-parameters`, using the keywords `:minimum-buffer-size` and `:maximum-buffer-size`. Currently, there is no way to control the behavior of local buffers. Since most of the allocation is from them, these settings are not really significant in SMP LispWorks. If the minimum size is too small, the system allocates buffers more frequently, thus slowing the program. Making the minimum too big causes more fragmentation, because small free blocks are not used. There is no easy way to determine the optimal values for the small objects buffer, except by experiment.

When there is an overflow the small object buffer is allocated in the big-chunk area, and then a bigger buffer is allocated (see below).

10.3.2.1 Allocation of static objects

Objects that cannot be moved are allocated in special segments, called static segments. These can be in any generation, but are in generation 2 by default.

Such objects include:

- Code that must not move during garbage collection, in particular the code and data of the GC itself
- Arrays created by `make-array` with *allocation :static*. This is the preferred way to allocate a static array.
- Objects allocated explicitly in the static area, by `in-static-area` or by use of `switch-static-allocation`.
- Foreign code loaded from a non-shared library via `link-load:read-foreign-modules`. This applies to LispWorks for UNIX only (not LispWorks for Linux, x86/x64 Solaris, FreeBSD or Macintosh).
- Objects allocated by `malloc`, `realloc` and `memalign` in foreign code loaded as above.

Because static objects are not allowed to move, the static segments are not allowed to move. This implies that if there is a static segment in a high address the image size cannot be reduced below this size. Applications that use a lot of static area normally allocate additional static segments, and thus grow without being able to shrink again. This can be prevented by enlarging the initial static segment, which is in a low address. Use the function `enlarge-static` to increase the size of the initial static segment. (Use `(room t)` to find its current size.)

10.3.2.2 Allocation in different generations

Objects that are known to have long life can be allocated directly in a higher generation, by using `allocation-in-gen-num` and `set-default-generation`. Note that both these functions have a global effect, that is any object allocated after a call to `set-default-generation` or within the body of `allocation-in-gen-num` is allocated in the specified generation, unless it is explicitly allocated in a different generation. Therefore careless use of these functions may lead to allocation of ephemeral garbage in high generations, which is very inefficient. Conversely, if a long-lasting object is allocated to a low generation, it has to survive several garbage collections before being automatically promoted to the next generation.

The best way to control the allocation generation for an array is to call `make-array` with `allocation :long-lived` or a number.

See also “Allocation of interned symbols and packages” on page 122 and “Allocation of stacks” on page 122.

10.3.3 GC operations

Mark and sweep is the basic operation of reclaiming memory, and it is done in two stages:

<i>Mark</i>	All objects that are alive in the generation being garbage collected and in younger generations are marked as alive. (Alive means pointed to by some other live object.)
-------------	--

<i>Sweep</i>	All unmarked objects in the generations being garbage collected are added to the free blocks, and all marked objects are unmarked.
--------------	--

A mark and sweep operation is always on all the generations from 0 to a specific number.

A mark and sweep operation can be caused explicitly by calling `gc-generation`.

Promotion is the process of moving objects from one generation to the next generation. An object is marked for promotion after surviving a specific number of mark and sweep operations, but may be promoted before that. The number of survivals is specific to each segment.

Promotion does not free objects.

10.3.4 Garbage collection strategy

When the GC runs out of memory, it has to find more memory. Normally (that is, when allocating in generation 0) the first operation is a mark and sweep. Before performing the mark and sweep, the GC compares the amount of memory allocated since the previous mark and sweep with the `:minimum-for-sweep` value, which is set by `set-gc-parameters`. If the amount allocated is less than `:minimum-for-sweep` the GC does not do a mark and sweep, but causes an overflow (described below). This prevents an excessive number of mark and sweep operations in periods when the program allocates a large amount of data which stays alive.

If more than `:minimum-for-sweep` has been allocated, a mark and sweep operation takes place. After this operation the GC checks that the segment it was trying to allocate to has more free space than the minimum free space for this segment. If the remaining free space is less than `minimum-free-space`, the GC tries to create more free space by promoting objects from the segment.

Before promoting, the GC performs two checks. First, it checks that there are enough objects marked for promotion to justify a promotion operation. The minimum free space for a segment is set by `set-minimum-free-space`, and can be shown by `(room t)`.

Second, the GC checks that there is enough free space in the next generation to accommodate the promoted objects. If there is insufficient space, the GC tries to free some, either by a mark and sweep on the next generation, promoting the next generation, or by enlarging the generation.

The minimum amount of space for promotion is the value `minimum-for-promote`, which is set by `set-gc-parameters`.

If there is insufficient space, and there are not enough objects marked for promotion, the GC increases the size of the image, by overflow, as described below.

On Motif only, note that the GC monitor window does not indicate a mark and sweep of generation 0, as this operation takes a small amount of time (it would take longer to change the display of the window). The GC monitor window appears only in the Motif IDE.

10.3.5 Overflow

If the amount allocated from the previous mark and sweep operation is less than `:minimum-for-sweep`, the GC does not perform a mark and sweep. Instead it allocates a small-objects buffer in the big-chunk area (the second segment in the first generation). The minimum and maximum sizes of this buffer are specified by `:minimum-overflow` and `:maximum-overflow`, which can be set by `set-gc-parameters`. If the GC fails to find a buffer of this size, it looks for a smaller buffer, and if that fails it enlarges the big-chunk area (and the process size) by the amount needed to allocate a buffer of the size of the currently allocated area in generation 0, up to a maximum amount specified by `:maximum-overflow`.

10.3.6 Behavior of generation 1

When objects are promoted from generation 0 to 1, and there is not enough space in generation 1, the GC tries to free space in generation 1. The first step is to check if sufficient space can be freed by promoting the objects marked for promotion. If this is the case the GC promotes these objects from generation 1 to generation 2. (In practice, this rarely happens.) If this check fails the GC marks and sweeps generation 1. If not enough space is freed by this mark and sweep, than either all the objects in generation 1 are promoted, or generation 1

is expanded. This is controlled by `expand-generation-1`, which specifies whether expansion or promotion takes place.

If generation 1 is expanded, the amount it tries to expand by is the value `:new-generation-size` (set by `set-gc-parameters`) in words (that is, multiples of 4 bytes), or the amount of free space needed, whichever is bigger. If `:new-generation-size` is 0, it is not expanded. In this case part of the objects marked for promotion are not promoted.

10.3.7 Behavior of generation 2

Normally generation 2 is not garbage collected. If the system runs out of space in this generation, it expands it, using the value of `:new-generation-size` multiplied by two. Garbage collection of generation 2 can be caused by calling the function `collect-generation-2` with appropriate argument.

10.3.8 Forcing expansion

If you know that a given generation will need to grow, you can save the GC the work by calling `enlarge-generation` to expand the generation in advance.

10.3.9 Controlling Fragmentation

Some applications periodically free (that is, stop using) a substantial amount of data that lived for long enough to reach generation 2 (use `room` or `room-values` and `generation-number` to follow the behavior of objects). In this case, `mark-and-sweep` should be called on generation 2, to collect these data and re-use the memory. Repeated cycles like this may cause fragmentation, which will slow down promotion into generation 2. This manifests itself in significant pauses, typically of a few seconds. `try-move-in-generation` or `try-compact-in-generation` can be used to reduce the fragmentation, and hence to reduce the pauses. Because these functions themselves take some time, they should be called when such a pause is acceptable.

'Moving' a segment means moving objects out of the segment to another segment, leaving the segment empty. This reduces the fragmentation in the generation, and it is normally much faster than compact. Therefore in almost all

cases, `try-move-in-generation` is better than `try-compact-in-generation`.

The actual decision to use these functions will be typically based on the results of `check-fragmentation`. For example, the following function checks if there is more than 10Mb free area in generation 2 in blocks of 4096 bytes or larger (`tlb`, third return value of `check-fragmentation`). If there is not, and the free area in generation 2 (`tf`) is more than four times the free area in large blocks, it calls `try-move-in-generation`. Because `try-move-in-generation` gets a *time-threshold* of 0, it returns after moving at most one segment. (It will not move any segments if none of them looks fragmented.)

```
(defun call-memory-functions()
  (gc-generation t)           ; first collect all dead objects
  (multiple-value-bind (tf tsb tlb)
    (check-fragmentation 2) ; check the fragmentation
    (when (and (> 10000000 tlb)
               (> (ash tf -2) tlb))
      (try-move-in-generation 2 0))))
```

A function such as this can be called at times when a pause of a few seconds is acceptable, and it will keep the memory of generation 2 unfragmented.

It is not possible to give definitive guidance here on how to use `try-move-in-generation` or `try-compact-in-generation`, because it depends on the way the application uses memory. In general, these functions will always improve the behavior of the application. Therefore the main problem is to identify points in the execution of the application where they can be called without causing unacceptably long pauses.

10.3.10 Summary of garbage collection symbols

The remainder of this chapter summarizes which functions are useful in which circumstances. See also “Common Memory Management Features” on page 122. For full details of these functions, see their reference entries.

10.3.10.1 Determining storage usage

To determine storage usage (useful when benchmarking), use the functions `room`, `total-allocation` and `find-object-size`. The function `room-values` is suitable for programmatic use: it returns the values that `room` prints.

In 32-bit LispWorks, `memory-growth-margin` returns the amount by which the Lisp heap can grow, if `set-maximum-memory` has been called.

10.3.10.2 Allocating in specific generations

Arrays can be allocated static or in a higher generation using the *allocation* argument in `make-array`.

To control the allocation of other objects to generations, use `allocation-in-gen-num`, `get-default-generation`, `set-default-generation` and `*symbol-alloc-gen-num*`.

10.3.10.3 Controlling a specific generation

To control the behavior of a specific generation, use `clean-generation-0`, `collect-generation-2`, `collect-highest-generation`, `expand-generation-1` and `set-minimum-free-space`.

10.3.10.4 Controlling the garbage collector

The functions that are most likely to be useful for controlling the GC are `room`, `check-fragmentation`, `gc-generation` (replacing `mark-and-sweep`) and `try-move-in-generation`.

Other potentially useful functions and macros are `avoid-gc`, `get-gc-parameters`, `gc-if-needed`, `enlarge-generation`, `normal-gc`, `set-gc-parameters`, `with-heavy-allocation` and `try-compact-in-generation`.

10.4 Memory Management in 64-bit LispWorks

This section describes the garbage collector (GC) in 64-bit LispWorks.

10.4.1 General organization of memory

The memory in 64-bit LispWorks is arranged in segments, which belong to generations. Unlike 32-bit LispWorks, segments are sparsely allocated in memory, that is they not contiguous.

Each segment has an allocation type, which defines the type of objects that the segment contains. The system creates and destroys segments as needed. A

generation may or may not contain a segment for a specific allocation type, and a generation may contain more than one segment for any particular allocation type. Segments may change in size.

You can see the allocation for each allocation type in the output of:

```
(room)
```

Additionally you can see the segments of each generation in the output of:

```
(room t)
```

After the total allocation in each generation, this prints the allocation type for each segment followed by the hexadecimal address range for allocating objects.

10.4.2 Segments and Allocation Types

Some GC interface functions take an allocation type as an argument, which is one of the keywords below. There are two categories of allocation type.

The main allocation types, which can be used as the *what* argument to the function `apply-with-allocation-in-gen-num`, are:

<code>:cons</code>	The segment contains only conses.
<code>:symbol</code>	The segment contains only symbols (and does not include symbol names or any of the other properties of symbols).
<code>:function</code>	The segment contains only function objects.
<code>:non-pointer</code>	The segment contains only objects that do not contain pointers (strings, specialized numeric arrays, double-floats).
<code>:other</code>	The segment contains other objects, that is any object that contain pointers, and is not a symbol, cons or a function.

The derived allocation types are:

:mixed	The segment contains a mixture of :other, :function and :symbol, but not :cons or :non-pointer.
:cons-static	The segment contains cons objects that are static.
:non-pointer-static	The segment contains objects that do not contain pointers and are static (currently stacks are also allocated in these segments).
:mixed-static	The segment contains a mixture like :mixed, but static.
:weak	The segment contains weak objects (arrays, and internals of weak hash tables).
:other-big	The segment contains a single very large simple vector. The vector is static.
:non-pointer-big	The segment contains a single very large non-pointer object (a string or a specialized numeric array). The vector is static.

Segments of allocation type :other-big or :non-pointer-big can be as large as required to hold their object.

For all other allocation types, the size of each single segment is restricted. The implementation limit is currently 256MB, and you can specify a smaller limit using `set-maximum-segment-size`.

10.4.3 Garbage Collection Operations

In 64-bit LispWorks there are two methods of garbage collection: *copy* (the default for all non-static objects) and *mark and sweep* (also referred to simply as *mark*) for static objects and under user control.

The two methods can be mixed within the same garbage collection operation and generation, but a segment is collected using only one of mark or copy in a given operation.

When a segment is collected using the copying method, the objects within it can either be copied to another segment in the same generation or can be cop-

ied to a segment in a higher generation. The latter case is called promotion. The automatic garbage collection copies with promotion until the objects reach the blocking generation, which is collected in a specific way as described in “Generation Management” on page 120.

10.4.4 Generation Management

In general, higher generations contain objects that live longer and are therefore much less likely to die. Each garbage collection only collects the generations up to some number, and never reclaims the objects in higher generations.

Objects move between generations by being promoted. For most allocation types, this means that the GC copies the objects from a segment in one generation to a segment in a higher generation. For allocation types `:other-big` and `:non-pointer-big`, the objects are not actually copied when they are promoted; but instead the whole segment is reattached to the higher generation. The automatic garbage collection promotes objects until they reach the blocking generation.

In the default configuration, there are 8 generations, numbered from 0 to 7. Generation 7 is used to keep objects that survived saving the image. Generations 4, 5 and 6 are not used. Generation 3 is the blocking generation, where long-lived objects accumulate. Generations 0, 1, and 2 are ephemeral, and objects that survive a garbage collection in each of these generations are promoted to the next generation.

10.4.5 Tuning the garbage collector

The GC settings are tuned for typical cases, so in general you do not need to change them. If you are considering tuning the GC, contact Lisp Support.

The main tools for seeing how the GC behaves are the macro `extended-time` and periodical calls to `room`.

In the output of `(room)` (or the more verbose `(room t)`), the allocation in each generation is presented according to the allocation type, which may be useful to decide on possible tuning.

`(extended-time forms)` outputs the time spent in garbage collection, whether automatic or called explicitly. The time is shown according to the

maximum generation number that was collected and to whether it was a standard garbage collection (automatic and calls to `gc-generation`) or a marking garbage collection (calls to `marking-gc`).

In addition to `room` and `extended-time`, there are also the functions `count-gen-num-allocation`, `gen-num-segments-fragmentation-state`, and `set-automatic-gc-callback`. These function can be used to collect information about automatic garbage collection operations.

The profiler can also help determine whether the settings can be improved for your application. See Chapter 11, “The Profiler” for details of that.

10.4.5.1 Interface for tuning the GC

The main interfaces are those which control the blocking generation.

For generations lower than the blocking generation, objects that survive are promoted, and the system does not automatically promote objects to higher generations. Thus if the application generates long-lived objects, they will accumulate in the blocking generation.

The behavior when the blocking generation grows is controlled by `set-blocking-gen-num` and `set-gen-num-gc-threshold`. It may also be useful to set the maximum segment size with `set-maximum-segment-size`.

Explicit garbage collection can be done by calling `gc-generation` and `marking-gc`. Since repeated use of `marking-gc` will cause a lot of fragmentation, the arguments `what-to-copy` and `max-size-to-copy` can be used to specify that part of the data should be collected by copying.

`gc-generation` can also be used to promote objects to a higher generation than the blocking generation.

It is normally less important to tune the ephemeral segments, that is the segments below the blocking generation. Functions that may be useful include `set-default-segment-size`, `set-spare-keeping-policy` and `set-delay-promotion`.

10.5 Common Memory Management Features

This section summarises Memory Management functionality common to all LispWorks 6.1 implementations.

10.5.1 Timing the garbage collector

The macro `extended-time` is useful when timing the GC.

10.5.2 Reducing image size

To reduce the size of the whole image, use `clean-down`.

In 32-bit LispWorks, you can use `(clean-down)` or the less aggressive `(clean-down nil)` to reduce the image size when the image is much larger than the amount that is allocated. In 64-bit LispWorks there is no need to do that.

10.5.3 Allocation of interned symbols and packages

Interned symbols (and their symbol names), and packages, are treated in a special way, because they are assumed to have a long life. They are allocated in the generation specified by the variable `*symbol-alloc-gen-num*`, which has the initial value 2 in 32-bit LispWorks and 3 in 64-bit LispWorks.

Symbols created with `make-symbol` or `gensym` start out in generation 0.

Symbols will be garbage collected if they are no longer accessible (regardless of property lists) but note that in 32-bit LispWorks, if the symbols are in generation 2 then you might need to invoke `mark-and-sweep` explicitly to collect them in a timely manner.

10.5.4 Allocation of stacks

Stacks are allocated directly in generation 2 because they are relatively expensive to promote. Therefore creating many processes will cause generation 2 to grow, even if these processes are short-lived.

The variable `*default-stack-group-list-length*` controls the number of stacks that are cached for reuse. Increase its value if your application repeatedly makes and discards more than 10 processes.

10.5.5 Mapping across all objects

To call a function on all objects in the image, use `sweep-all-objects`.

10.5.6 Special actions

You may want to perform special actions when certain types of object are garbage collected, using the functions `add-special-free-action`, `flag-special-free-action`, `flag-not-special-free-action` and `remove-special-free-action`.

For example, when an open file stream is garbage collected, the file descriptor must be closed. This operation is performed as a special action.

10.5.7 Garbage collection of foreign objects

Users of the Foreign Language Interface may want to specify the allocation of static arrays. The recommended way to do this is to call `make-array` with `:allocation :static`. See for example `:lisp-array` in the *LispWorks Foreign Language Interface User Guide and Reference Manual*.

10.5.8 Freeing of objects by the GC

Weak arrays and weak hash tables can be used to allow the GC to free objects.

Relevant functions are `make-hash-table`, `set-hash-table-weak`, `set-array-weak`, `make-array` and `copy-to-weak-simple-vector`.

For a description of weak vectors see `set-array-weak`, page 651.

10.6 Assisting the garbage collector

This section describes techniques that may improve the performance of your application by reducing the GC's workload.

10.6.1 Breaking pointers from older objects

This is a technique that can be useful when older objects regularly point to newer objects in a lower generation. In such a case, when the lower generation (only) is collected these newer objects will be promoted even if the older objects are not live. All of these objects will not get collected until the higher generation is collected.

This is a general issue with generational garbage collection and, if it causes poor performance in your application, can be addressed along these lines. It is not necessarily a problem in every case where older objects point to newer objects.

For example, suppose you are popping items from a queue represented as a list of conses (or other structures), then you can set the "next" slot of each popped item to `nil`.

In the code below, if the `queue-head` cons is promoted to generation n , then all the other conses will also be promoted to generation n eventually, until generation n is collected. This happens even after calls to `pop-queue` have removed these conses from the queue.

```
(defstruct queue head tail)

(defun push-queue (item queue)
  (let ((new (cons item nil)))
    (if (queue-head queue)
        (setf (cdr (queue-tail queue)) new)
        (setf (queue-head queue) new))
    (setf (queue-tail queue) new)))

(defun pop-queue (queue)
  (pop (queue-head queue)))
```

The fix is to make `pop-queue` set the "next" slot (in this case the `cdr`) of the discarded `queue-head` cons to `nil`, so that it no longer points from an older object to a newer object. For example:

```
(defun pop-queue (queue)
  (when-let (head (queue-head queue))
    (setf (queue-head queue) (shiftf (cdr head) nil))
    (car head)))
```

11

The Profiler

The LispWorks profiler provides a way of empirically monitoring execution characteristics of Lisp programs. The data obtained can help to improve the efficiency of a Lisp program by highlighting those procedures which are commonly used or particularly slow, and which would therefore benefit from optimization effort.

11.1 What the profiler does

With the profiler running, the Lisp process is interrupted regularly at a specified time interval until the profiler is turned off. Having halted the execution of the process the profiler scans the execution stack and records information about it, including the names of all functions found. A special note is made of which function is at the top of the stack. After profiling stops the profiler can present a report containing a call tree and/or a cumulative columnar report.

The columnar report shows aggregated information about each function as follows:

- The number of times the function was called.
- The number of times the function was found on the stack by the profiler, both in absolute terms and as a percentage of the total number of scans of the stack.

- The number of times the function was found on the top of the stack, both in absolute terms and as a percentage of the total number of scans of the stack.

The call tree shows name of a root function and a "tree" of callee functions below it. To the right of each function's name the number of times it was seen on the stack under a particular caller is shown, along with the percentage this represents of the total number of times the function was seen.

The call tree is more computationally expensive to record than the cumulative data. You can choose whether to record and output the call tree, as described in the next section.

11.2 Setting up the profiler

Before a profiling session can start several parameters must be set, using the function `set-up-profiler`. There are four main areas to consider: the symbols to be profiled, the time interval between samples, the kind of profiling required, and the format of the output.

- It is possible to keep track of every function called during a particular computation, but significant effort is involved in determining which symbols are suitable for profiling and in keeping track of the results. To minimize this effort you need to specify which symbols to profile, either by naming the required symbols, or by naming a package, all of whose symbols are profiled. The profiler first checks that these symbols have indeed got function definitions and are therefore suitable for profiling.
- You might want to specify the time interval between interrupts. The resolution of this value is clearly dependent on the operating system. In most cases the default value, 10ms, is adequate. This number is important, because with these statistical methods of program profiling the accuracy of the results increases with the number of samples taken.
- On Unix/Linux/FreeBSD systems the kind of profiling required may be set. This refers to what kind of time is monitored in order to determine when to interrupt the Lisp process. There are three possibilities for how the time interval is measured:

The time the Lisp process is actually executing plus the time that the system is executing on behalf of the process. This is called *profile time*.

Just the time that the process is actually executing. This is called *virtual time*.

The actual elapsed time, called *real time*.

- The output can be presented as a tree of calls seen and a columnar report (`style :tree`), or just the columnar report (`style :list`). You can restrict the data shown in several ways, helping you to focus on the slowest parts of your program.

Below is an example of setting up the profiler:

```
(set-up-profiler :symbols '(car cdr) :style :list)
```

Here the functions `car` and `cdr` are going to be profiled and the output will be just the columnar report.

The function `set-up-profiler` adds symbols to the `*profile-symbol-list*`. The functions `add-symbol-profiler` and `remove-symbol-profiler` can also be used to change the symbols profiled.

The function `set-profiler-threshold` can be used with `reset-profiler` to control the effects of repeated profiler runs.

11.3 Running the profiler

The profiler has two distinct modes. You can use both in the same session, but not at the same time.

To use either mode, you must first call `set-up-profiler` to load the profiler and set its parameters including the output format.

The macro `profile` simply profiles all processes while a body of code is run, as described in “Using the macro profile” on page 128. Start profiling this way if you don’t see a need to use the alternate mode.

Alternatively the functions `start-profiling`, `stop-profiling` and `set-process-profiling` offer programmatic control over when profiling occurs and which processes are profiled. This is described in “Programmatic control of profiling” on page 128.

The function `do-profiling` is a convenience function which allows you to profile multiple threads using `start-profiling` and `stop-profiling`.

11.3.1 Using the macro profile

To profile your Lisp forms enter:

```
(profile <forms>)
```

This evaluates the forms as an implicit `progn` and prints the results, according to the parameters established by `set-up-profiler`.

Note: you cannot use `profile` (or the graphical Profiler tool) after a call to `start-profiling` and before a call to `stop-profiling` with `print t`, because the two profiling modes are incompatible.

11.3.2 Programmatic control of profiling

Your program can control profiling. This is useful when you want to profile only a part of the program.

In your program, call `start-profiling` start collecting profiling information. Call `stop-profiling` with `print nil` to temporarily stop collecting, or call `stop-profiling` with `print t` to stop collecting and print the results. At any point you can call `set-process-profiling` to modify the set of processes for which profiling information is being (or will be) collected.

For example:

```
; ; start profiling, current process only
(start-profiling :processes :current)
(do-interesting-work)
; ; temporarily suspend profiling
(stop-profiling :print nil)
(do-uninteresting-work)
; ; resume profiling
(start-profiling :initialize nil)
(do-more-interesting-work)
; ; now, all processes are interesting
(set-process-profiling :set :all)
(do-some-more-interesting-work)
; ; stop profiling and print the results
(stop-profiling)
```

Note: you cannot call `start-profiling` inside the scope of the macro `profile` or while the graphical Profiler is profiling, because the two profiling modes are incompatible.

11.4 Profiler output

A typical report would be:

```

profile-stacks called 564 times

Call tree
Symbol          seen   (%)
 1: MOD          17 ( 3)
 2: FLOOR        5 ( 1)
 1: EQL          8 ( 1)
 1: >=           7 ( 1)
 2: REALP        2 ( 0)
 1: +             6 ( 1)
 1: LENGTH       4 ( 1)

Cumulative profile summary
Symbol      called  profile   (%)      top   (%)
MOD         1000000    17 ( 3)      8 ( 1)
EQL         2000117     8 ( 1)      8 ( 1)
>=          1000001     7 ( 1)      5 ( 1)
+            1000000     6 ( 1)      6 ( 1)
FLOOR        1000000     5 ( 1)      5 ( 1)
LENGTH       2000086     4 ( 1)      4 ( 1)
REALP        1000001     2 ( 0)      2 ( 0)

Top of stack not monitored 93% of the time

```

The first line means that Lisp was interrupted 564 times by the profiler.

The call tree shows that in 17 of these interrupts (3% of them) the profiler found the function `mod` on the stack, in 5 of these interrupts it found the function `floor` on the stack, and so on. Moreover, `floor` only appears under the `mod` branch of the tree, which means that each of these times `floor` was called by `mod`.

The cumulative profile summary also shows how many times each symbol was found on the stack. Moreover it shows that the function `mod` was called 1000000 times, the function `eq1` was called 2000117 times, and so on. (Note: this information is not collected on Intel-based platforms by default.) In 17 of these interrupts it found the function `mod` on the stack, and on 8 of these occasions `mod` was on the top of the stack. You can deduce that 526 times the function on the top of the stack was none of those reported.

You can control sort order of the cumulative profile summary with `print-profile-list`.

11.5 Interpretation of profiling results

One important figure is the amount of time it was found on top of the stack in the cumulative profile summary. Just because a function is found on the stack does not mean that it uses up much processing time, but if it is found consistently on the top of the stack then it is likely that this function has a significant execution time. Another thing to check is that you expect the functions near to top of the call tree to take significant time.

It must be remembered that the numbers produced are from random samples and thus it is important to be careful in interpreting their meaning. The rate of sampling is always coarse in comparison to the function call rate and so it is possible for strange effects to occur and significant events to be missed. For example, “resonance” may occur when an event always occurs between regular sampling times, though in practice this does not appear to be a problem.

11.6 Profiling pitfalls

Profiling should only be attempted on compiled code. If it is done on interpreted code, the interpreter itself is profiled, and this distorts the results for the actual Lisp program.

Macros cannot be profiled as they are expanded during the compilation process. Similarly some Common Lisp functions may be present in the source code but not in the compiled code as they are transformed by the compiler. For example:

```
(member 'x '(x y z) :test #'eq)
```

is transformed to:

```
(memq 'x '(x y z))
```

by the compiler and therefore the function `member` is never called.

Recursive functions need special attention. A recursive function may well be found on the stack in more than one place during one interrupt. The profiler counts each occurrence of the function. Hence the total number of times a

function is found on the stack may be much greater than the number of times the stack is examined.

Care must be taken when profiling structure accessors. Structure accessors compile down into a call to a closure of which there is one for all structure setters and one for all structure getters. Therefore it is not possible to profile individual structure setters or getters by name.

It must be remembered that even though a function is found on the stack this does not mean that it is active or that it is contributing significantly to the execution time. However the function found on the top of the stack is by definition active, and thus this is the more important value.

It is quite possible that the amount of time the top symbol is monitored is significantly less than 100% despite the profiler being set to profile all the known functions of the application. This is because at the time of the interrupt an internal system function may well be on the top of the stack.

It is possible to profile all the symbols in the system by setting up the profiler as follows:

```
(set-up-profiler :package (list-all-packages))
```

11.7 Profiling and garbage collection

The macro `extended-time` provides useful information on garbage collection activities.

The `gc` argument of `set-up-profiler` controls whether or not the system's memory management functions are profiled.

12

Customization of LispWorks

This chapter gives examples of how to make changes to LispWorks to make it more suitable for use by you and your colleagues.

12.1 Introduction

12.1.1 Pre-loading code

You can save an image with changes pre-loaded. This is suitable for changes you want to share with other users of that image, and for code which takes some time to load. It cannot be used to alter settings which the system makes automatically on startup.

“Saving a LispWorks image” on page 135 describes how to do this.

12.1.2 Loading code at start up

You can also load changes each time you start LispWorks. This is suitable for code which loads quickly. For changes only you want to see, put the code in your personal initialization file. For changes to share with other users at your site, put the code in your site initialization file.

“Initialization files” on page 134 describes these initialization files.

12.1.3 Specific customizations

The remainder of this chapter describes some customizations, all of which can be saved in an image or placed in an initialization file, as needed. You can use both techniques: stable code including patches is saved in the image, whilst experimental or fast-loading code is loaded via the initialization file.

12.2 Configuration and initialization files

There are a number of files that contain configuration and initialization information:

12.2.1 Configuration files

- The LispWorks file `config/configure.lisp` contains many default configuration settings. You can create a customized copy of this file when you install LispWorks, as described in the *LispWorks Release Notes and Installation Guide*.
- The LispWorks file `config/key-binds.lisp` gives the default editor key bindings for Emacs emulation.
- The LispWorks file `config/mac-key-binds.lisp` gives the editor key bindings for Mac OS editor emulation, if supported on your platform.
- The LispWorks file `config/msw-key-binds.lisp` gives the editor key bindings for Microsoft Windows editor emulation, if supported on your platform.

12.2.2 Initialization files

- The LispWorks file `config/siteinit.lisp` is the default site initialization file. The distributed file loads any supplied patches.
- You may also have a personal initialization file which is loaded on startup. By default LispWorks looks for a file called `.lispworks` in your home directory, although you can change its name and location (see “Setting Preferences” in the *LispWorks IDE User Guide*).

The default location of your home directory varies on Unix systems, but it is typically something like `/home`. On Windows, the directory is constructed from the environment variables HOMEDRIVE and HOME-
PATH. The directory itself has the same name as your user name, so if you log on as `john`, your home directory might be `/home/john` on Unix systems or something like `C:\Documents and Settings\john` on Windows XP.

A sample personal initialization file, the LispWorks file `config/a-dot-lispworks.lisp`, is supplied. You should create a customized copy of this file when you install LispWorks, as described in the *LispWorks Release Notes and Installation Guide*.

12.3 Saving a LispWorks image

There are two ways to save an image with changes pre-loaded.

- This section describes the traditional method, using a configuration file and `save-image` script.
- “Saved sessions” on page 137 describes how to save a session, which allows restoring your windowing environment as well as your Lisp objects.

12.3.1 The configuration file

First create a file `my-configuration.lisp` containing the settings you want in your saved image. You may want to change some of the pre-configured settings shown in `config/configure.lisp`, add customizations from the rest of this chapter, or load your application code.

12.3.2 The save-image script

Now create a `save-image` script which is a file `save-image.lisp` containing something like:

```
(in-package "CL-USER")
(load-all-patches)
(load #-mswindows "/tmp/my-configuration.lisp"
      #+mswindows "C:/temp/my-configuration.lisp")
#+:cocoa
(compile-file-if-needed
 (sys:example-file
  "configuration/macos-application-bundle")
 :load t)
(save-image #+:cocoa
  (write-macos-application-bundle
   "/Applications/LispWorks 6.1/My LispWorks.app")
 #:-:cocoa "my-lispworks")
```

The script shown loads `my-configuration.lisp` from a temporary directory. You may need to modify this.

12.3.3 Save your new image

The simplest way to save your new image is to use the Application Builder tool in the LispWorks IDE. Start the Application Builder as described in the *LispWorks IDE User Guide*, enter the path of your `save-image` script in the **Build script:** pane, and press the **Build the application using the script** button.

Alternatively you can run LispWorks in a command interpreter and pass your `save-image` script in the command line as shown below.

- On Macintosh, run in Terminal.app:

```
mymac$ "/Applications/LispWorks 6.1/LispWorks.app/Contents/MacOS/
lispworks-6-1-0-macos-universal" -build save-image.lisp
```

Your new application bundle is saved in `/Applications/LispWorks 6.1/My LispWorks.app`

- On Microsoft Windows, run in a MS-DOS window:

```
C:\temp\>"C:\Program Files\LispWorks\lispworks-6-1-0-x86-
win32.exe" -build save-image.lisp
```

Your new LispWorks image is saved in `C:\temp\my-lispworks.exe`.

- On Linux, run in a shell:

```
linux:/tmp$ lispworks-6-1-0-x86-linux -build save-image.lisp
```

Your new LispWorks image is saved in `/tmp/my-lispworks`.

For other platforms and for 64-bit LispWorks the image name varies from that shown, but the principle is the same.

12.3.4 Use your new image

Your new LispWorks image contains the settings you specified in `my-configuration.lisp` pre-loaded.

You can add further customizations on start up via the initialization files mentioned in “Initialization files” on page 134.

Note that your newly saved image runs itself, not a saved session.

12.3.5 Saving a non-GUI image with multiprocessing enabled

To create an image which does not start the LispWorks IDE automatically, make a `save-image` script, for example in `/tmp/resave.lisp`, containing:

```
(in-package "CL-USER")
(load-all-patches)
(save-image "~/lw-console"
  :console t
  :multiprocessing t
  :environment nil)
```

Run LispWorks like this to create the new image `~/lw-console`:

```
lispworks-6-1-0-x86-linux -build /tmp/resave.lisp
```

12.4 Saved sessions

You can save a LispWorks session, which can be restarted at a later date. This allows you to resume work after restarting your computer.

Saving sessions is intended for users of the LispWorks IDE. The graphical tools described in *LispWorks IDE User Guide* provide the best way to use and configure session saving. However it is also possible to save a session programmatically, which is described in this section.

When you save a session, LispWorks performs the following three steps:

1. Closing all windows and stopping multiprocessing.

2. Saving an image. On Mac OS X this creates an application bundle.
3. Restarting the LispWorks IDE and all of its windows.

If a saved session is run later, then it will redo the last step above, but see “What is saved and what is not saved” on page 138 for restrictions.

Sessions are stored on disk as LispWorks images, by default within your personal application support folder (the exact directory varies between operating systems).

12.4.1 The default session

There is always a default session, which is used when you run the supplied LispWorks image.

When you run any other image directly, including a saved session or an image you created with `save-image`, it runs itself (not the default session).

Saved sessions are platform and version specific. In particular, a 32-bit LispWorks saved session cannot be the default session for 64-bit LispWorks, or vice-versa.

12.4.2 What is saved and what is not saved

All Lisp code and data that was loaded into the image or was created in it is saved. This includes all editor buffers, the Listener history and the value of `*`, `**` and `***`.

All threads are killed before saving, so any data that is accessible only through a `mp:process`, or by a dynamically bound variable, is not accessible.

All windows are closed, so any data that is accessible only within the windowing system is not accessible after saving a session.

The windows are automatically re-opened after saving the session and all Lisp data within the CAPI panes is retained.

External connections (including open files, sockets, database connections and COM interfaces) become invalid when the saved session is restarted. In the image from which the session was saved, the connections are not explicitly affected but if these connections are thread-specific, they will be affected because the thread is killed. In recreated Shell tools the command history is

recovered but the side effects of those commands are not. Debugger and Stepper windows are not re-opened because they contain the state of threads that have been killed.

12.4.3 Saving a session programmatically

You can save a session by calling `save-current-session`

12.4.3.1 Save Session actions

The first thing that `save-current-session` does is to execute the action-list "Save Session Before".

After redisplaying all the interfaces, the action-list "Save Session After" is executed. That happens both in the saving invocation and the restarting saved image.

12.4.3.2 Non-IDE interfaces

If there are non-IDE interfaces on the screen when `save-current-session` is invoked, these interfaces are destroyed in the first step, and displayed again in the third step. Note that the display will occur in a different thread than the one running the interface before the saving (which was killed in the first step).

If the interface (or any of its children) contains information that is normally destroyed (in some sense) in the `destroy-callback`, this information can be preserved over a call to `save-current-session` by defining methods on the generic functions `capi:interface-preserving-state-p` or `capi:interface-preserve-state`.

12.4.4 Saving a session using the IDE

You can save a session or set up periodic automatic session saving using the configuration tools in the LispWorks IDE. See "Session Saving" in the *LispWorks IDE User Guide* for details.

12.5 Load and open your files on startup

Suppose you always compile and load several files after LispWorks starts. You can arrange for this to happen automatically by adding forms like these in your initialization file:

```
(defvar *my-files*
  '("/path/to/fool"
    "/path/to/foo2"
    "/path/to/foo3"))

(dolist (file *my-files*)
  (compile-file file :load t))
```

If you also want to open these files in the Editor tool, then you can add this form in your initialization file, after those above:

```
(define-action "Initialize LispWorks Tools"
  "Open My Files"
  #'(lambda (screen)
      (declare (ignore screen))
      (dolist (file *my-files*)
        (ed file))))
```

12.6 Customizing the editor

This section explains some of the customizations you can make to the Editor tool in the LispWorks IDE.

12.6.1 Controlling appearance of found definitions

The commands `Find Source`, `Find Source for Dspec` and `Find Tag` retrieve the file containing a definition and place it in a buffer with the relevant definition visible. By default, the start of the definition is in the middle of the Editor window and is highlighted.

The variable `editor:*source-found-action*` controls the position and highlighting of the found definition. The value should be a list of length 2.

The first element controls the positioning of the definition, as follows:

t	Show it at the top of the editor window.
---	--

A non-negative fixnum

Position it that many lines from the top.

`nil` Position it at the center of the window.

The second element can be `:highlight`, meaning highlight the definition, or `nil`, meaning don't.

For example, to configure the editor so that found definitions are positioned at the top of the window and are not highlighted, do

```
(setq editor:*source-found-action* '(t nil))
```

This variable is set in the file `a-dot-lispworks.lisp`.

12.6.2 Specifying the number of editor windows

You can specify the maximum number of editor windows that are present at any one time. For example, to set the maximum to 1:

```
(setq editor:*maximum-ordinary-windows* 1)
```

This variable is set in the file `a-dot-lispworks.lisp`.

12.6.3 Binding commands to keystrokes

You can bind existing editor commands to different keystrokes, using `editor:bind-key`.

The LispWorks file `config/key-binds.lisp` is supplied. It shows the standard Emacs key bindings for LispWorks.

The following example shows how to rebind `?` so that it behaves as an ordinary character in the echo area of tools in the LispWorks IDE — this can be useful if your symbol names include question marks.

```
(editor:bind-key "Self Insert" #\? :mode "Echo Area")
```

Since `?` is then no longer available for help, you may wish to rebind help to `Ctrl+?`.

```
(editor:bind-key "Help on Parse" #\C-? :mode "Echo Area")
```

If you use another editor emulation, then see the LispWorks file `config/msw-key-binds.lisp` or `config/mac-key-binds.lisp` for the corresponding `editor:bind-key` forms.

12.7 Finding source code

Note: This section does not apply to LispWorks Personal Edition.

To configure LispWorks so that editor commands such as `Find Source`, the menu command `Find Source`, and the dspec system are able to locate definitions in the supplied editor source code:

1. Load the logical host for the editor source code:

```
(load-logical-pathname-translations "EDITOR-SRC")
```

2. Configure source finding to know about editor source code:

```
(setf dspec:*active-finders*
      (append dspec:*active-finders*
              (list "EDITOR-SRC:editor-tags-db")))
```

3. Now do (for example) `Meta+X Find Command Definition` and enter `Wfind File`.

The definition of the command `wfind File` is displayed in an Editor tool.

See “Controlling appearance of found definitions” on page 140 for information on controlling how the source code is displayed.

12.8 Controlling redefinition warnings

By default most system-provided definers such as `c1:defun`, `c1:deffmacro`, `c1:deffmethod` and so on signal a warning when they redefine an existing definition. You can bind or set `*redefinition-action*` to eliminate such warnings or make it signal error instead.

Also, the system is configured to protect symbols in implementation packages against definition and redefinition. For example, an error is signalled if you attempt to put a function definition on the symbol `c1:*read-base*`. This behavior is configurable by the variables `*handle-warn-on-redefinition*` and `*packages-for-warn-on-redefinition*`. Bear in mind that the default

configuration protects the stability of the system, so if you need to prevent such errors it is better to bind one or both of these variables around specific defining forms, rather than setting their global values.

12.9 Specifying the initial working directory

The working directory is set on startup and provides the default location for the **File > Open...** dialog. Call **change-directory** in your initialization file (see “Initialization files” on page 134) to control the initial working directory.

12.10 Using ! for :redo

The default way of redoing the previous command from the command history is via **:redo**. If you want to use **!** (exclamation mark) instead of **:redo**, add the following to your **.lispworks** file:

```
(set-macro-character #\!
  #'(lambda (stream char)
    '(:redo))
```

You may wish during some sessions to reset **!** back to its normal role as a character. To do this, evaluate:

```
(set-syntax-from-char #\! #\@)
```

12.11 Customizing LispWorks for use with your own code

This section contains some information on customizations you can make in order to make developing your own code a little easier.

12.11.1 Preloading selected modules

If you frequently use some code that is normally supplied as separate modules, you can load them at start-up time from your initialization file. This file is called **.lispworks** by default, but can be changed to be any other filename. See “Setting Preferences” in the *LispWorks IDE User Guide* for details.

For example, to load the dynamic-completion code every time you start LispWorks, include the following in your initialization file.

```
(require "dynamic-complete")
```

12.11.2 Creating packages

When writing your own code that uses, for instance, the `capi` package, create a package of your own that uses `capi` — do not work directly in the `capi` package. By doing this you can avoid unexpected name clashes.

12.12 Structure printing

By default `defstruct` generates a method on `print-object`. You can avoid this by binding at macroexpansion time the variable `structure:*defstruct-generates-print-object-method*`.

12.13 Configuring the printer

This section applies only on Unix/Linux/FreeBSD platforms.

You can configure your LispWorks image for your printer, by selecting **File > Printer Setup** from any tool with printing capacities, for example the editor, and choosing **Add Printer**.

When configuring a printer, the CAPI printing library prompts for a *PostScript Printer Description* file (PPD), which defines such things as the paper size and the printable area of the page, in the form of a standard PostScript language header. The printing code splices this file into the PostScript produced from submitting a CAPI printing request.

The library on the LispWorks CD contains a generic PPD file, called `generic.ppd`, that defines these values conservatively to ensure that it should work with most printers. For accurate results, you should use the PPD supplied with your printer.

The PPD files are placed in the `ppd` subdirectory of the `postscript` directory in the `lispworks` library directory. Files added to the `ppd` directory are expected to have the extension ".`ppd`".

12.13.1 PPD file details

A PPD file contains a description of the attributes and capabilities of a given printer, such as paper sizes supported, the printable area of the page, the number and names of input paper trays, optional features such as additional paper

trays or duplex units, and so on, together with the printer-specific PostScript language commands necessary to use the features.

The `generic.ppd` file defines a simple generic printer supporting A4, A3, US letter, and US legal paper sizes, and supporting manual feed. It defines conservative margins (1 inch all round), and the documents generated should be compatible with most PostScript printers. It is suitable for producing PostScript files when the destination printer is unknown, and may also be used if the appropriate PPD for the printer is not available.

However, for the best results, we recommend the use of the appropriate PPD for the printer. This allows you to specify which optional features (if any) have been installed on the printer, and ensures that the Print dialog provides access to appropriate printer capabilities such as multiple input trays and duplex printing. This also ensures that the CAPI uses the correct values for the printable areas of the page.

13

LispWorks as a dynamic library

This chapter describes how to create a dynamic library or DLL from LispWorks and discusses use of the library.

13.1 Introduction

You can use 32-bit LispWorks to build a dynamic library on Microsoft Windows, Intel Macintosh, Linux, x86/x64 Solaris and FreeBSD, and 64-bit LispWorks on Windows, Intel Macintosh, Linux and x86/x64 Solaris.

To do this, use `save-image` or `deliver` and supply a list value for *dll-exports*. On platforms other than Windows passing *dll-added-files* also creates a dynamic library.

The result is a library that cannot be executed on its own, but can be dynamically loaded by another process. On Windows this is done with the Windows APIs `LoadLibrary` and then `GetProcAddress`. On other platforms the dynamic library can be loaded by `dlopen` and then `dlsym`.

The dynamic library is usually of file type `dll` on Windows, `dylib` on Macintosh and `so` on Linux, x86/x64 Solaris or FreeBSD. The first implementation of this functionality in LispWorks was on Microsoft Windows only, therefore the terminology that is used is sometimes Windows-like. In particular “DLL” refers to any dynamic library.

A program that loads a LispWorks dynamic library must be compiled and linked as follows:

Linux	Link with <code>libpthread.so</code>
FreeBSD	Link with <code>libpthread.so</code>
Mac OS X	No special requirements
Solaris	Compile and link multi-threaded (for example, using the <code>-mt</code> option to Oracle's <code>cc</code>)

13.2 Creating a dynamic library

To deliver a LispWorks runtime as a dynamic library supply a list value for *dll-exports* when calling `deliver`.

To save a LispWorks image as a dynamic library supply a list value for *dll-exports* when calling `save-image`.

Additionally on Linux, x86/x64 Solaris, Macintosh and FreeBSD platforms, you can supply a list value for *dll-added-files* to deliver or save a dynamic library.

Note: a LispWorks dynamic library is licensed in the same way as a LispWorks executable.

13.2.1 C functions provided by the system

When LispWorks is a dynamic library the functions described in Chapter 45, “Dynamic library C functions” are automatically available. They allow the loading process control over relocation and unloading of the library.

13.2.2 C functions provided by the application

dll-exports specifies application-defined exported functions in a LispWorks dynamic library.

Exports can also be provided in the files named in *dll-added-files*, on Linux, x86/x64 Solaris, Macintosh and FreeBSD platforms.

13.2.3 Example

This script saves an image `hello.dll` which is a Windows DLL:

```
----- hello.lisp -----
(in-package "CL-USER")
(load-all-patches)
;; The signature of this function is suitable for use with
;; rundll32.exe.
(fli:define-foreign-callable ("Hello"
                               :calling-convention :stdcall)
  ((hwnd w:hwnd)
   (hinst w:hinstance)
   (string :pointer)
   (cmd-show :int))
  (capi:display-message "Hello world"))

(save-image "hello"
            :dll-exports '("Hello")
            :environment nil)
-----
```

Run the script by

```
lispworks-6-1-0-x86-win32.exe -build hello.lisp
```

on the command line, or use the Application Builder tool.

(See “Saving a LispWorks image” on page 135 for more information about how to save an image.)

You can test the DLL by running

```
rundll32 hello.dll,Hello
```

on the command line.

To see the dialog, you may need to dismiss the LispWorks splashscreen first.

13.3 Initialization of the dynamic library

Each of the exports specified via *dll-exports* ensure first that LispWorks has finished initializing. If initialization has not yet started, they start the initialization process themselves. This is true regardless of the value of *automatic-init* (see below).

A LispWorks dynamic library is initialized automatically on loading, or not, according to the value of *automatic-init* in the call to `deliver` or `save-image`.

13.3.1 Automatic initialization

On Microsoft Windows when *automatic-init* was true the initialization finishes before the Windows function `LoadLibrary` returns, and if LispWorks fails for some reason then the call to `LoadLibrary` fails too.

On other platforms when *automatic-init* was true, during the automatic initialization `dlopen` just causes the initialization to start and returns immediately. The initialization will finish sometime later. The LispWorks function `LispWorksState` can be used to check whether it finished initializing.

Automatic initialization is useful when the dynamic library is something like a server that does not communicate by function calls. On Windows it also allows `LoadLibrary` to succeed or fail according to whether the LispWorks dynamic library initialized successfully or not.

13.3.2 Initialization via `InitLispWorks`

Not using automatic initialization (that is, creating the dynamic library with *automatic-init nil*) allows using `InitLispWorks` to relocate the image if necessary, and do any other initialization that may be required.

13.4 Relocation

LispWorks normally maps its heap on startup in the same place that it was when it was saved, and when it needs more memory it maps this nearby. This applies when LispWorks is a dynamic library as well as for LispWorks executables.

This mapping can cause memory clashes with other software, which may be avoided by relocating LispWorks. Most of the LispWorks implementations are relocatable though the details vary between platforms and between 32-bit LispWorks and 64-bit LispWorks.

On Microsoft Windows and Macintosh, LispWorks detects and avoids memory clashes automatically. On other platforms, you can relocate a LispWorks dynamic library (for all the relocatable implementations) if necessary by a

suitable call to `InitLispWorks` as described in “Startup relocation” on page 314.

13.5 Multiprocessing in a dynamic library

Multiprocessing is started automatically in a LispWorks dynamic library. Therefore you can arrange for Lisp initialization operations by adding process specifications to `*initial-processes*`.

For example, if you have a function like this:

```
(defun my-server ()  
  (let ((s (establish-a-socket)))  
    (loop (accept-connection s))))
```

you need to do something like:

```
(pushnew '("My server" () my-server) mp:*initial-processes*  
        :test 'equalp)
```

before saving or delivering your library.

13.6 Unloading a dynamic library

Before a LispWorks dynamic library is unloaded, LispWorks should be made to ‘quit’ cleanly, allowing it to clean up resources that it uses.

When the LispWorks dynamic library is loaded by a main process which you (the LispWorks programmer) do not control, then use `dll-quit`. If you control the main process, then use `QuitLispWorks` instead. For the details, see the respective manual entries for `dll-quit` and `QuitLispWorks`.

14

The Metaobject Protocol

LispWorks CLOS essentially supports the metaobject protocol described in chapters 5 & 6 of *The Art of the Metaobject Protocol* (Kiczales, des Rivières & Bobrow, The MIT Press, 1991). Throughout the LispWorks documentation, “AMOP” refers to this book. Users might find it helpful to refer to the relevant chapters online at <http://www.lisp.org/mop/>.

All the LispWorks MOP symbols are in the `clos` package.

There are some discrepancies between LispWorks and AMOP, which are described in this Chapter.

This Chapter also describes some common problems encountered by programmers using the MOP.

14.1 Metaobject features incompatible with AMOP

14.1.1 Instance Structure Protocol

The generic functions implementing slot access are like those described in AMOP, except that each takes a *slot-name* argument rather than a slot definition object, and the primary methods are therefore specialized differently.

For details, see `slot-boundp-using-class`, `slot-value-using-class` and `slot-makunbound-using-class`.

Note: by default, standard slot accessors are optimized to not call `slot-value-using-class`. This can be overridden with the `:optimize-slot-access` class option. See the second definition of `virtual-metaclass` below for an example of the use of this.

`standard-instance-access` is not supported as defined in AMOP. Note that there is an internal function of the same name, but this is not optimal. Also, `funcallable-standard-instance-access` is not supported. An alternative for fast instance access is to use the `:optimize-slot-access` class option.

14.1.2 Method Metaobjects

`standard-reader-method`, `standard-accessor-method` and `standard-writer-method` all have a required `:slot-name` initarg, rather than a `:slot-definition` initarg as specified in AMOP.

Compatibility note: in LispWorks 4.3 and previous versions, `accessor-method-slot-definition` was not implemented. This is implemented in the current version.

14.1.3 Method Lambdas

LispWorks `make-method-lambda` is not AMOP-compatible. It takes separate *lambda-list* and *body* arguments, and the returned `lambda` form is different to that specified in AMOP (see “Method Functions” on page 154 below).

LispWorks does not support user defined methods for the generic function `make-method-lambda`.

14.1.4 Method Functions

LispWorks method functions take the same arguments as the method itself, whereas in AMOP they take a list of arguments and a list of next methods.

14.1.5 EQL specializers

`eql-specializer`, `eql-specializer-object` and `intern-eql-specializer` are not implemented.

`eql` specializers in LispWorks are lists.

14.1.6 Generic Function Invocation Protocol

`compute-applicable-methods-using-classes` is not implemented.

`compute-discriminating-function` is implemented and returns the discriminator but:

- It does not use `compute-applicable-methods-using-classes` since LispWorks does not have that function.
- It does not call `compute-applicable-methods`.

Moreover `add-method` does not call `compute-discriminating-function` because this would be inefficient when doing multiple calls to `add-method`. Instead, `compute-discriminating-function` is called when the generic function is called.

14.1.7 Method combinations

`method-combination` objects do not contain the arguments, merely the type. There is a single `method-combination` object per type.

Therefore the value returned by `generic-function-method-combination`, and the default value of the `:method-combination` initarg, and the `:method-combination` argument processed by `ensure-generic-function-using-class` are specific only to the type of the method combination.

Also, `find-method-combination` is not implemented.

14.1.8 Compatible metaclasses

The AMOP defines that the standard primary method for `validate-super-class` should return true if the class of one of the arguments is `standard-class` and the class of the other is `funcallable-standard-class`.

In LispWorks, objects of these metaclasses are not completely compatible, so `validate-superclass` will return false in these cases.

Beware that defining a class that mixes `standard-class` and `funcallable-standard-class` can lead to inconsistencies with the predicate `functionp`, the type `function` and the class `function`.

14.1.9 Inheritance Structure of Metaclass Classes

`funcallable-standard-object` is implemented as defined in AMOP, except that its class precedence list has direct superclasses

```
(function standard-object)
```

rather than

```
(standard-object function)
```

so that LispWorks is compliant with the ANSI Common Lisp rules.

For details, see `funcallable-standard-object`, page 338.

14.2 Common problems when using the MOP

14.2.1 Inheritance across metaclasses

Usually an inherited class is of the same metaclass as the parent class.

For other kinds of inheritance, you need to define a method on `validate-superclass` which returns true when called with the respective metaclasses. For example:

```
(defclass mclass-1 (standard-class)
  ())

(defclass mclass-2 (standard-class)
  ())

(defclass a ()
  ()
  (:metaclass mclass-1))

(defmethod validate-superclass
  ((class mclass-2)
   (superclass mclass-1))
  t)

(defclass b (a)
  ()
  (:metaclass mclass-2))
```

Without the `validate-superclass` method, the last form signals an error because `mclass-1` is an invalid superclass of `mclass-2`.

14.2.2 Accessors not using structure instance protocol

By default, `defclass` creates optimized standard accessors which do not call `slot-value-using-class`.

This optimization is controlled by the `defclass` option `:optimize-slot-access`, which defaults to `t`.

There is an illustration of this effect of `:optimize-slot-access` in the example below.

14.2.3 The MOP in delivered images

Issues with MOP code that occur only in delivered LispWorks images are documented in the section “Delivery and the MOP” in the *LispWorks Delivery User Guide*.

14.3 Implementation of virtual slots

This is an implementation of virtual slots with readers, writers and which also allow access by `slot-value`.

```

;; ----- Virtual Slots -----
(in-package "CL-USER")

;; Metaclass of objects that might contain virtual slots.

(defclass virtual-metaclass (standard-class)
  ()
  )

;; Mixin metaclass for virtual slots and methods to make them
;; appear virtual.

(defclass virtual-slot-definition
  (standard-slot-definition)
  ((function :initarg :function
             :accessor virtual-slot-definition-function)))
  )

(defmethod slot-definition-allocation
  ((slotd virtual-slot-definition))
  :virtual)

(defmethod (setf slot-definition-allocation)
  (allocation (slotd virtual-slot-definition))
  (unless (eq allocation :virtual)
    (error "Cannot change the allocation of a ~S"
          'virtual-direct-slot-definition))
  allocation)

;; Class of direct virtual slots and methods to construct them
;; when appropriate.

(defclass virtual-direct-slot-definition
  (standard-direct-slot-definition
   virtual-slot-definition)
  ()
  )

;; Called when the class is being made, to choose the metaclass of
;; a given direct slot. It should return the class of slot
;; definition required.

(defmethod clos:direct-slot-definition-class
  ((class virtual-metaclass) &rest initargs)
  ;; Use virtual-direct-slot-definition if appropriate.
  (if (eq (getf initargs :allocation) :virtual)
      (find-class 'virtual-direct-slot-definition)

```

```

        (call-next-method)))

;; Called when the defclass is expanded, to process a slot option.
;; It should return the new list of slot options, based on
;; already-processed-options.

(defmethod clos:process-a-slot-option
    ((class virtual-metaclass) option value
     already-processed-options slot)
  ;; Handle the :function option by adding it to the
  ;; list of processed options.
  (if (eq option :function)
      (list* :function value already-processed-options)
      (call-next-method)))

;; Class of effective virtual slots and methods to construct
;; them when appropriate.

(defclass virtual-effective-slot-definition
    (standard-effective-slot-definition
     virtual-slot-definition)
  ()
  )

;; Called when the class is being finalized, to choose the
;; metaclass of a given effective slot.  It should return the
;; class of slot definition required.

(defmethod clos:effective-slot-definition-class
    ((class virtual-metaclass) &rest initargs)
  ;; Use virtual-effective-slot-definition if appropriate.
  (let ((slot-initargs (getf initargs :initargs)))
    (if (member :virtual-slot slot-initargs)
        (find-class 'virtual-effective-slot-definition)
        (call-next-method)))

(defmethod clos:compute-effective-slot-definition
    ((class virtual-metaclass)
     name
     direct-slot-definitions)
  ;; Copy the function into the effective slot definition
  ;; if appropriate.
  (let ((effective-slotted (call-next-method)))
    (dolist (slotted direct-slot-definitions)
      (when (typep slotted 'virtual-slot-definition)
        (setf (virtual-slot-definition-function effective-slotted)

```

```

(virtual-slot-definition-function slotd))
  (return)))
effective-slotd))

;; Underlying access methods for invoking
;; virtual-slot-definition-function.

(defmethod clos:slot-value-using-class
  ((class virtual-metaclass) object slot-name)
  (let ((slotd (find slot-name (class-slots class)
                      :key 'slot-definition-name)))
    (if (typep slotd 'virtual-slot-definition)
        (funcall (virtual-slot-definition-function slotd)
                 :get
                 object)
        (call-next-method)))))

(defmethod (setf clos:slot-value-using-class)
  (value (class virtual-metaclass) object slot-name)
  (format t "~% setf slot : ~A" slot-name)
  (let ((slotd (find slot-name (class-slots class)
                      :key 'slot-definition-name)))
    (if (typep slotd 'virtual-slot-definition)
        (funcall (virtual-slot-definition-function slotd)
                 :set
                 object
                 value)
        (call-next-method)))))

(defmethod clos:slot-boundp-using-class
  ((class virtual-metaclass) object slot-name)
  (let ((slotd (find slot-name (class-slots class)
                      :key 'slot-definition-name)))
    (if (typep slotd 'virtual-slot-definition)
        (funcall (virtual-slot-definition-function slotd)
                 :is-set
                 object)
        (call-next-method)))))

(defmethod clos:slot-makunbound-using-class
  ((class virtual-metaclass) object slot-name)
  (let ((slotd (find slot-name (class-slots class)
                      :key 'slot-definition-name)))
    (if (typep slotd 'virtual-slot-definition)
        (funcall (virtual-slot-definition-function slotd)
                 :unset
                 object)
        (call-next-method)))))

```

```

          object)
(call-next-method)))))

(defmethod clos:slot-exists-p-using-class
  ((class virtual-metaclass) object slot-name)
(or (call-next-method)
  (and (find slot-name (class-slots class)
             :key 'slot-definition-name)
       t)))

;; Example virtual slot which depends on a real slot.
;; Compile this separately after the virtual-metaclass etc.

(defclass a-virtual-class ()
  ((real-slot :initarg :real-slot :accessor real-slot
              :initform -1)
   (virtual-slot :accessor virtual-slot
                 :initarg :virtual-slot
                 :allocation :virtual
                 :function
                 'a-virtual-class-virtual-slot-function))
  (:metaclass virtual-metaclass))

(defun a-virtual-class-virtual-slot-function
  (key object &optional value)
  (ecase key
    (:get (let ((real-slot (real-slot object)))
            (if (<= 0 real-slot 100)
                (/ real-slot 100.0)
                (slot-unbound (class-of object)
                              object
                              'virtual-slot))))
    (:set (setf (real-slot object) (* value 100))
          value)
    (:is-set (let ((real-slot (real-slot object)))
              (<= real-slot 100)))
    (:unset (setf (real-slot object) -1))))
;; ----- Virtual Slots -----

```

Compile the code above. Then make an object and access the virtual slot:

```

CL-USER 1 > (setf object (make-instance 'a-virtual-class))
#<A-VIRTUAL-CLASS 2067B064>

CL-USER 2 > (setf (virtual-slot object) 0.75)

      setf slot : VIRTUAL-SLOT
0.75

CL-USER 3 > (virtual-slot object)
0.75

CL-USER 4 > (real-slot object)
75.0

```

Note that when you call `(setf real-slot)` there is no output since `(setf clos:slot-value-using-class)` is not called. Compare with `(setf virtual-slot)`.

```

CL-USER 5 > (setf (real-slot object) 42)
42

```

Redefine `a-virtual-class` with `:optimize-slot-access nil`:

```

CL-USER 6 > (defclass a-virtual-class ()
               ((real-slot :initarg :real-slot
                           :accessor real-slot
                           :initform -1)
                (virtual-slot :accessor virtual-slot
                           :initarg :virtual-slot
                           :allocation :virtual
                           :function
                           'a-virtual-class-virtual-slot-function))
               (:metaclass virtual-metaclass)
               (:optimize-slot-access nil))

Warning: (DEFCLASS A-VIRTUAL-CLASS) being redefined in LISTENER
(previously in H:\tmp\vs.lisp).
Warning: (METHOD REAL-SLOT (A-VIRTUAL-CLASS)) being redefined in
LISTENER (previously in H:\tmp\vs.lisp).
Warning: (METHOD (SETF REAL-SLOT) (T A-VIRTUAL-CLASS)) being
redefined in LISTENER (previously in H:\tmp\vs.lisp).
Warning: (METHOD VIRTUAL-SLOT (A-VIRTUAL-CLASS)) being redefined
in LISTENER (previously in H:\tmp\vs.lisp).
Warning: (METHOD (SETF VIRTUAL-SLOT) (T A-VIRTUAL-CLASS)) being
redefined in LISTENER (previously in H:\tmp\vs.lisp).
#<VIRTUAL-METACLASS A-VIRTUAL-CLASS 21AD908C>

```

Now the standard accessors call `slot-value-using-class`, so we see output when calling `(setf real-slot)`

```
CL-USER 7 > (setf (real-slot object) 42)

  setf slot : REAL-SLOT
  42
```

15

Multiprocessing

LispWorks supports “lightweight” processes. The programming environment, for example, makes extensive use of this mechanism to create separate processes for the various tools.

On Microsoft Windows, Mac OS X, Linux, x86/x64 Solaris and FreeBSD, LispWorks multiprocessing uses native threads and supports Symmetric Multiprocessing (SMP). The implementation is referred to as "SMP LispWorks" where relevant.

On other platforms LispWorks uses a single native thread and implements user level threads. The implementation is referred to as "non-SMP LispWorks" where relevant.

15.1 Introduction to processes

A process (sometimes called a thread) is a separate execution context. It has its own call stack and its own dynamic environment.

A process can be in one of three different states: *running*, *waiting*, and *inactive*. When a process is *waiting*, it is still active, but is waiting for the system to wake it up and allow its computation to restart. A process that is *inactive* has stopped, because it has an arrest “reason”.

For a process to be active (that is, running or waiting), it must have at least one run reason and no arrest reasons. If, for example, it was necessary to temporarily stop a process, it could temporarily be given an arrest reason. However the arrest reason mechanism is not commonly used in this manner.

The process that is currently executing is termed “the current process”. The function `get-current-process` gets the current process, and is the preferred way of doing so. The variable `*current-process*` is normally bound to the same process, except inside a wait function when it is called by the scheduler.

The current process continues to be executed until either it becomes a waiting process by calling a Process Wait function as described in “Process Waiting” on page 182, or it allows itself to be interrupted by calling `process-allow-scheduling` (or its current timeslice expires and it involuntarily relinquishes control).

In SMP LispWorks all processes that are not waiting are running as far as LispWorks is concerned, and are scheduled by the operating system to the available CPUs.

In non-SMP LispWorks, the system runs the waiting process with the highest priority. If processes have the same priority then the system treats them equally and fairly. This is called round robin scheduling.

The simplest way to create a process is to use `process-run-function`. This creates a process with the specified name which commences by applying the specified function to arguments. `process-run-function` returns immediately and the newly created process runs concurrently.

15.2 The process programming interface

15.2.1 Creating a process

To create a new process, use `process-run-function`.

15.2.2 Finding out about processes

The system initializes a number of processes on startup. These processes are specified by `*initial-processes*`.

The current process is specified by `*current-process*`. A list of all the current processes is returned by `list-all-processes` and the number of them is returned by `processes-count`. The function `ps` is analogous to the UNIX command `ps`, and returns a list of the processes in the system, ordered by priority.

To find a process when you know its name, use `get-process`. To find the name, when you have the process, use `process-name`. The variable `*process-initial-bindings*` specifies the variables that are initially bound in a process.

15.2.3 Process Priorities

Each process has a priority and can either be runnable, blocked or suspended.

The effect of process priorities is significantly different between SMP LispWorks and non-SMP LispWorks.

15.2.3.1 Process priorities in SMP LispWorks

Process priorities are almost completely ignored in SMP LispWorks.

The main exception is that for processes that wait with `process-wait` for something to happen, a process with higher priority is likely to wake up earlier, but even then it is not guaranteed.

15.2.3.2 Process priorities in non-SMP LispWorks

If there is a runnable process with priority P, then no processes with priority less than P will run. When there are runnable processes with equal priority, they will be scheduled in a round-robin manner.

If a process with priority P is running and a blocked process with priority greater than P becomes runnable, the second process will run when the scheduler is next invoked (either explicitly or at the next preemption tick).

To find the priority of a process, use `process-priority`. This can be changed using `change-process-priority`.

```
(mp:change-process-priority proc-1 10)
```

Another way to specify the priority is to create the process with `process-run-function`, passing the keyword `:priority`:

```
(list
  (mp:process-run-function
    "SORTER-DOT" '(:priority 10) #'sorter #\.)
  (mp:process-run-function
    "SORTER-DASH" () #'sorter #\--))
```

15.2.4 Interrupting a process

To interrupt a running process, use `process-interrupt` or `process-kill`. To break a process and enter the debugger, use `process-break`.

To suspend a process until a predicate is `t`, use `process-wait`, `process-wait-with-timeout`, `process-wait-local`, `process-wait-local-with-timeout`, `process-wait-local-with-timeout-and-periodic-checks` or `process-wait-local-with-timeout-and-periodic-checks`. The function `process-wait-function` returns a function that specifies a reason for the process waiting.

Note: The `process-wait*` functions need to be called from the process you want to suspend.

15.2.5 Blocking interrupts

The purpose of blocking interrupts is to prevent a process aborting in the middle of an operation that needs to be completed. A typical example is the cleanup forms of an `unwind-protect`.

Blocking interrupts does not provide atomicity. Other processes may continue to execute.

Blocking interrupts limits the control that LispWorks has over the processes, so interrupts should not be blocked except when necessary. However, apart from blocking interrupts in a process it does not affect the behavior of the system.

The following macros and functions allow control over blocking interrupts: `allowing-block-interrupts`, `with-interrupts-blocked`, `current-process-unblock-interrupts` and `current-process-block-interrupts`.

Additionally the macros `unwind-protect-blocking-interrupts` and `unwind-protect-blocking-interrupts-in-cleanups` allow your program to prevent interrupts from stopping cleanup forms from completing.

Compatibility note: In LispWorks 5.1 and previous versions, `mp:without-preemption` and `mp:without-interrupts` are sometimes used to block interrupts, but they also provide atomicity. In many cases (probably most), they are used to provide atomicity, and in these cases they cannot be replaced by blocking interrupts. To get atomicity in LispWorks 6.0 and later you need to use locks or atomic operations. To get atomicity while debugging, you can also use `with-other-threads-disabled`.

15.2.6 Old interrupt blocking APIs removed

The macros `mp:without-interrupts` and `mp:without-preemption`, which were available in LispWorks 5.1 and earlier, are no longer supported. The semantics of these macros allowed them to be used for several different purposes, which now require specific solutions.

- Atomic operations. This use was designed to make operations atomic with respect to other uses of the same macro or with respect to some other unquantified operations that were expected to be atomic, such as reading or writing a single slot in an object. Code of this kind should be converted to use locks (see “Locks” on page 179) or low level atomic operations (see “Low level atomic operations” on page 192).
- Complete operations. This use was designed to ensure that a set of operations completed without being interrupted by `mp:process-interrupt`, keyboard breaks and so on. See “Blocking interrupts” on page 168 for the new approach.

The following subsections show examples of typical uses of the old interrupt blocking APIs together with their replacements. The examples use `mp:without-interrupts` but the ideas also apply to uses of `mp:without-preemption`.

15.2.6.1 Atomic increment

Old:

```
(without-interrupts  
  (incf *global-counter*))
```

New: use low level atomic operations.

```
(sys:atomic-incf *global-counter*)
```

15.2.6.2 Atomic push/pop

Old:

```
(without-interrupts  
  (push value *global-list*))  
  (without-interrupts  
    (pop *global-list*))
```

New: use low level atomic operations.

```
(sys:atomic-push value *global-list*)  
  
(sys:atomic-pop *global-list*)
```

15.2.6.3 Atomic push/delete

Old:

```
(without-interrupts  
  (push value *global-list*))  
  (without-interrupts  
    (setq *global-list* (delete value *global-list*)))
```

New: use a lock, because delete cannot be done atomically since it reads more than one object before modifying one of them.

```
(defvar *global-list-lock* (mp:make-lock :name "Global List"))  
  
(mp:with-lock (*global-list-lock*)  
  (push value *global-list*))  
  
(mp:with-lock (*global-list-lock*)  
  (setq *global-list* (delete value *global-list*)))
```

15.2.6.4 Atomic plist update

Old:

```
(without-interrupts
  (setf (getf *global-alist* key) value))
  (without-interrupts
    (getf *global-alist* key))
```

New: use a lock, because a plist consists of more than one object so cannot be updated with low level atomic operations.

```
(defvar *global-alist-lock* (mp:make-lock :name "Global Plist"))

(mp:with-lock (*global-alist-lock*)
  (setf (getf *global-alist* key) value))

(mp:with-lock (*global-alist-lock*)
  (getf *global-alist* key))
```

15.2.6.5 Atomic update of a data structure

The example below is a resource object, which maintains a count of free items and also list of them. These two slots must stay synchronized.

Old:

```
(without-interrupts
  (when (plusp (resource-free-item-count resource))
    (decf (resource-free-item-count resource))
    (pop (resource-free-items resource))))
```

New: use a lock, because more than one slot has to be updated, so cannot be updated with low level atomic operations.

```
(mp:with-lock ((resource-lock resource))
  (when (plusp (resource-free-item-count resource))
    (decf (resource-free-item-count resource))
    (pop (resource-free-items resource))))
```

15.2.6.6 Atomic access to a cache in a hash table

Old:

```
(without-interrupts
  (or (gethash value *global-hashtable*)
      (setf (gethash value *global-hashtable*)
            (make-cached-value))))
```

New: use the hash table lock.

```
(hcl:with-hash-table-locked
  *global-hashtable*
  (or (gethash value *global-hashtable*)
      (setf (gethash value *global-hashtable*)
            (make-cached-value))))
```

Alternative new: use the hash table lock only if the value is not already cached. This can be faster than the code above, because it avoids locking the hash table for concurrent reads.

```
(or (gethash value *global-hashtable*); probe without the lock
    (hcl:with-hash-table-locked
      *global-hashtable*
      (or (gethash value *global-hashtable*); reread with the lock
          (setf (gethash value *global-hashtable*)
                (make-cached-value)))))
```

15.2.7 Multiprocessing

To start multiprocessing, use `initialize-multiprocessing`. This function does not return until multiprocessing has terminated.

It is not necessary to use `initialize-multiprocessing` when the LispWorks environment is already running. Note that, on Windows, Mac OS X, Linux, x86/x64 Solaris and FreeBSD, the LispWorks images shipped do start the programming environment. If you create an image which does not start the programming environment, by using the `:environment nil` argument to `save-image`, then multiprocessing can be started in this new image as described below.

15.2.7.1 Starting multiprocessing interactively

You can call `initialize-multiprocessing` from the REPL interface, which generates a default Listener process if no other processes are specified by `*initial-processes*`.

15.2.7.2 Multiprocessing on startup

There are three ways to make a LispWorks executable start multiprocessing on startup.

1. Use the `-multiprocessing` command line argument

2. Save an image which starts multiprocessing by doing

```
(save-image "mp-lispworks"
  :restart-function 'mp:initialize-multiprocessing)
```

3. Use delivery to create the executable and pass the argument:**:multiprocessing t** to **deliver**. The delivery function will be called automatically in a new process. See the *LispWorks Delivery User Guide* for more details.

LispWorks dynamic libraries always start multiprocessing on startup. See “Multiprocessing in a dynamic library” on page 151 for more information.

In all cases, ***initial-processes*** can be used to control which processes are created on startup, as described in “Running your own processes on startup” on page 173.

Note: On Windows, Linux, x86/x64 Solaris, FreeBSD and Mac OS X you cannot save a LispWorks image with multiprocessing running.

15.2.7.3 Running your own processes on startup

initial-processes is a list of lists. Each list is used by the system as a set of arguments to **process-run-function**. During initializing multiprocessing, the system does this:

```
(dolist (x mp:*initial-processes*)
  (apply 'mp:process-run-function x))
```

This script saves a LispWorks image which starts multiprocessing on restart and runs a user-defined process.

```
(load-all-patches)
(load "my-server-code")
(push '("Start Server" () start-my-server)
      mp:*initial-processes*)
(save-image "my-server"
  :remarks "My Server"
  :restart-function 'mp:initialize-multiprocessing
  :environment nil)
```

See **save-image**, page 638 for a description of how to save an image.

15.2.8 Values across processes

This section describes ways to pass or read values in another process.

15.2.8.1 Returning a value from another process

Rather than using global variables to pass values between processes, you can use closures instead. For example:

```
(defun send-with-result (process function)
  (let ((remote-result :none))
    (flet ((resultp ()
            (listp remote-result)))
      (run-it ()
        (setq remote-result
              (multiple-value-list (funcall function))))))
      (mp:process-send process (list #'run-it))
      (mp:process-wait "Waiting for result" #'resultp)
      (values-list remote-result))))
```

15.2.8.2 Accessing symbol values across processes

Use `symeval-in-process` to read the value of a dynamically bound symbol in a given process.

`(setf mp:symeval-in-process)` can set the value of such a symbol.

`symeval-in-process` is mostly intended for debugging. Do not call it while the thread is actually running.

15.2.9 Stopping and unstopping processes

This section describes a typical way of using `process-stop` and `process-unstop`.

Suppose a pool of "worker" processes is managed by a "manager" process. A process in the worker pool marks itself as available for work, and then calls `process-stop`. The manager process later finds a worker process that is marked as available for work, puts the work in a place known to the worker process, and then calls `process-unstop` on the worker process.

For this scheme to work properly, the check of whether the worker is available needs to include a call to `process-stopped-p`. Otherwise, it is possible for the following sequence of events to occur:

1. A worker marks itself as available.
2. The manager process finds the worker and gives it the work.
3. The manager process calls `process-unstop` on the worker.
4. The worker process proceeds and calls `process-stop`, and never wakes up.

To guard against this possibility, then the manager should call `process-stopped-p` when finding the worker in the second step above. Alternatively, it could check the result of `process-unstop`.

15.2.10 Example

The following example allows two (or more) multiplication tables to be printed out simultaneously.

First, the function to print out a multiplication table.

```
(in-package "USER")

(defun print-table (number total stream)
  (do ((i 1 (+ i 1)))
    ((> i total))
    (format stream "~S X ~S = ~S~%" number i (* i number))
    (mp:process-allow-scheduling)))
```

Note the use of `process-allow-scheduling` to allow the process to be interrupted once during each iteration of the do loop.

Now we define the function that calls `print-table` within multiprocessing:

```
(defun process-print-table (name number total)
  (mp:process-run-function name nil
    #'print-table number total *standard-output*))
```

The `nil` argument is used because no keywords are specified.

`process-print-table` can now be called from two separate Listener windows to print out different multiplication tables simultaneously, for example:

```
(process-print-table "t1" 5 50)
```

in one Listener and:

```
(process-print-table "t2" 6 50)
```

in another Listener.

15.3 Atomicity and thread safety of the LispWorks implementation

Access to all Common Lisp objects is thread safe in the sense that it does not cause an error because of threading issues.

15.3.1 Immutable objects

Immutable (or read-only) objects such as numbers, characters, functions, pathnames and restarts can be freely shared between threads.

15.3.2 Mutable objects supporting atomic access

This section outlines for which types of mutable Common Lisp object access is atomic. That is, each value read from the object will correspond to the state at some point in time. Note however, that if several values are read, there is no guarantee about how these values will relate to each other if they are being modified by another thread (see “Issues with order of memory accesses” on page 178).

When one of these mutable atomic objects is modified, readers see either the old or new value (not something else), and it is guaranteed that the Lisp image is not corrupted by the modification even if multiple threads read or write the object simultaneously.

Access to conses, simple arrays except arrays with element type of integer with less than 8 bits, symbols, packages and structures is atomic. Note that this does not apply to non-simple arrays.

Slot access in objects of type `standard-object` is atomic with respect to modification of the slots and and with respect to class redefinition.

`vector-pop`, `vector-push`, `vector-push-extend`, (`setf fill-pointer`) and `adjust-array` are all atomic with respect to each other, and with respect to other access to the array elements.

The Common Lisp functions that access hash tables are atomic with respect to each other. See also `modify-hash` for atomic reading and writing an entry and `with-hash-table-locked`.

Access to packages is atomic.

Note that pathnames cannot be modified, and therefore access to them is always atomic.

Access to synchronization objects (mailboxes, barriers, semaphores and condition variables) is atomic. More information about these objects is in “Synchronization between threads” on page 185.

Operations on editor buffers (including points) are atomic and thread-safe as long as their arguments are valid. This includes modification to the text. However, buffers and points may become invalid because of execution on another thread. The macros `editor:with-buffer-locked` and `editor:with-point-locked` should be used around editor operations on buffers and points that may be affected by other processes. Note that this is applicable also to operations that do not actually modify the text, because they can behave inconsistently if the buffer they are looking at changes during the operation. See the *LispWorks Editor User Guide* for details of these macros.

15.3.3 Mutable objects not supporting atomic access

This section outlines for which types of mutable Common Lisp object access is not atomic.

Access to arrays with element type of integer of less than 8 bits is not guaranteed to be atomic.

Access to non-simple arrays is not guaranteed to be atomic.

Access to lists (including alists and plists) is not atomic. Lists are made of multiple cons objects, so although access to the individual conses is atomic, the same does not hold for the list as a whole.

Sequence operations which modify multiple elements are not atomic.

Macros that expand to multiple accesses are in general not atomic. In particular, modifying macros like `push` and `incf` are not atomic (but see the atomic versions of some of them in “Low level atomic operations” on page 192).

Making several calls to Common Lisp functions that access hash tables will not be atomic overall. See also `modify-hash` for atomic reading and writing an entry and `with-hash-table-locked`.

Stream operations are in general not atomic. There is an undocumented interface for locking of streams when this is required - contact Lisp Support if you need this.

Operations on CAPI objects are not atomic in general. The same is true for anything in the IDE. These operations need to be invoked from the thread that owns the object, for example by `capi:execute-with-interface` or `capi:apply-in-pane-process`.

15.3.4 Issues with order of memory accesses

When multiple threads access the same memory location, the order of those accesses is not generally guaranteed. You should therefore not attempt to implement “lockless algorithms” which depend on the order of memory accesses.

However, all of the atomic operations and locking operations in this chapter do ensure that all memory accesses that happen before them have finished and that all memory accesses that happen after them start after them. Therefore, normally there is nothing special to consider when using these operations. The modification check macros `with-modification-change` and `with-modification-check-macro` also take care of this.

15.3.5 Single-thread context arrays and hash-tables

Access to hash tables and non-simple arrays can be improved where they are known to be accessed in a single thread context. That is, only one thread at the same time accesses them.

The `make-hash-table` argument `single-thread` tells `make-hash-table` that the table is going to be used only in single thread context, and therefore does not need to be thread-safe. Such a table allows faster access.

Similarly the `make-array` argument *single-thread* creates an array that is single threaded. Currently, the main effect of *single-thread* is on the speed of `vector-pop`, `vector-push`, and `vector-push-extend` on non-simple vectors. These operations are much faster on "single threaded" vectors, typically more than twice as fast as "multi-threaded" vectors.

You can also make an array be "single-threaded" with `set-array-single-thread-p`.

The result of parallel access to a "single-threaded" vector is unpredictable.

15.4 Locks

Locks can be used to control access to shared data by several processes.

The two main symbols used in locking are the function `make-lock`, to create a lock, and the macro `with-lock`, to execute a body of code while holding the specified lock.

A lock has a name (a string) and several other components. The printed representation of a lock shows the name of the lock and whether it is currently locked. Additionally if the lock is locked it shows the name of the process holding the lock, and how many times that process has locked it. For example:

```
#<MP:LOCK "my-lock" Locked 2 times by "My Process" 2008CAD8>
```

The function `lock-owner` returns the process that locked a given lock.

The function `lock-name` returns the name of a lock.

The function `process-lock` blocks the current process until a given lock is claimed or a timeout passes, and `process-unlock` releases the lock.

The macro `with-lock` executes code with a lock held, and releases the lock on exit, as if by `process-lock` and `process-unlock`.

If you need to avoid blocking on a lock that is held by some other thread, then use `with-lock` with *timeout* 0, like this:

```
(unless (mp:with-lock (lock nil 0)
  (code-to-run-if-locked)
  t)
  (code-to-run-if-not-locked))
```

The macros `with-sharing-lock` and `with-exclusive-lock` can be used with sharing locks.

15.4.1 Features of lock APIs for SMP

Locks can be marked as recursive or not recursive, and they can be made sharing or exclusive. There are APIs for querying whether a lock can be, or actually is, locked recursively.

There are some guarantees about the lock and unlock functions.

15.4.1.1 Recursive and sharing locks

The keyword argument `recursivep` to `make-lock`, when true, allows the lock to be locked recursively. `recursivep` is true by default. If `recursivep` is false then trying to lock again causes an error. This is useful for debugging code where the lock is not expected to be claimed recursively.

The keyword argument `sharing` to `make-lock`, when true, creates an "sharing" lock object, which supports sharing and exclusive locking. A sharing lock is handled by different functions and methods. See `with-exclusive-lock`, `with-sharing-lock`, `process-exclusive-lock`, `process-exclusive-unlock`, `process-sharing-lock` and `process-sharing-unlock`.

15.4.1.2 Querying locks

See `lock-recursive-p`, `lock-owned-by-current-process-p`, `lock-owner`, `lock-locked-p` and `lock-recursively-locked-p`.

15.4.2 Guarantees and limitations when locking and unlocking

In compiled code `process-lock`, `process-exclusive-lock` and `process-sharing-lock` are guaranteed to return if they locked their argument. In other words there will not be any throw between the time they locked the lock and the time they return. That means that in compiled code the next form will at least start executing, and if it is an `unwind-protect` the cleanup forms will at least start executing. (If the code is evaluated, this is not guaranteed.) "Locking" here also means incrementing the count of a lock that is already held by the current thread.

However these functions may throw before locking. For example, in the following code `process-lock` may throw without locking, for example because something interrupts the process by `process-interrupt`:

```
(unwind-protect
  (progn (mp:process-lock lock)
         (whatever))
  (mp:process-unlock lock))
```

If this call to `process-lock` does throw without locking, then `process-unlock` will be called on a lock that is not locked.

The correct code that guarantees (when compiled) that `process-unlock` is called on exit only when `process-lock` did lock is:

```
(mp:process-lock lock)

(unwind-protect
  (whatever)
  (mp:process-unlock lock))
```

Conversely, `process-unlock`, `process-exclusive-unlock` and `process-sharing-unlock` guarantee to successfully unlock the lock, but are not guaranteed to return.

For example, the following code may fail to call `another-cleanup`:

```
(mp:process-lock lock)

(unwind-protect
  (whatever)
  (mp:process-unlock lock)
  (another-cleanup))
```

If `another-cleanup` is essential to execute in all throws, it needs its own `unwind-protect`:

```
(mp:process-lock lock)

(unwind-protect
  (whatever)
  (unwind-protect
    (mp:process-unlock lock)
    (another-cleanup)))
```

Note: the guarantees described in this section are relevant only in compiled code.

15.5 Process Waiting

Process Waiting means that a process suspends its own execution until some condition is true. The generic Process Wait functions take a *wait-function* argument, which is arbitrary though somewhat restricted Lisp code. A process resumes running when the *wait-function* returns true. The specific Process Wait functions wait for a specific condition.

15.5.1 Specific Process Wait functions

For communication between processes, these are:

`mailbox-read`, `process-wait-for-event` and `mailbox-wait-for-event`.

For synchronization, these are:

`condition-variable-wait` and `barrier-wait`, also `semaphore-acquire` and `semaphore-release`.

For locking these are:

`process-lock`, `process-exclusive-lock` and `process-sharing-lock`.

For sleeping, these are:

`cl:sleep` and `current-process-pause`.

15.5.2 Generic Process Wait functions

The generic Process Wait functions are:

`process-wait` and `process-wait-with-timeout`

`process-wait-local` and `process-wait-local-with-timeout`

`process-wait-local-with-periodic-checks` and `process-wait-local-with-timeout-and-periodic-checks`.

Note: For brevity we sometimes refer to "the `*-periodic-checks` functions" or "the `*-with-timeout` functions".

All the generic Process Wait functions take *wait-reason* and *wait-function* arguments and potentially also arguments to pass to the *wait-function*. The **-with-timeout* functions mentioned above also take a *timeout* argument. The **-periodic-checks* functions also take a *period* argument.

The *wait-reason* is used only to mark the process as waiting for something for debugging purposes. It does not affect the behavior of the functions.

The generic Process Wait functions "wake up" (that is, they simply return to the caller) either when the timeout passed (if they take a *timeout* argument), or when the wait function returns true. The three pairs of functions mentioned above differ in the mechanism that calls the wait function.

`process-wait` and `process-wait-with-timeout` arrange that the "scheduler" will call the wait function when it runs. The "scheduler" is invoked at various points, in an indeterminate process. The advantage of this is that the programmer does not need to worry too much about when the wait function is going to be called. In non-SMP LispWorks (that is, LispWorks 5.1 and earlier) the programmer does not need to worry at all: when some process sets up something that would make the wait function return true, the waiter process could not run anyway until the setting-up process stopped for some reason (including preemption), by which time the scheduler would have called the wait function if it had not done it before. In SMP LispWorks (that is, LispWorks 6.0 and later), these two processes can run simultaneously, so the delay between the setting up and the scheduling is not necessary. It can be avoided by "poking" the waiting process with `process-poke`, if the waiting process is known, or by invoking the scheduler by `process-allow-scheduling`.

Note: All the specific Process Wait functions record that they wait, and the operations that allow them to continue implicitly "poke" the waiting process.

A large disadvantage of `process-wait` and `process-wait-with-timeout` is that their *wait-function* is called by the "scheduler" in an indeterminate process. That means that the wait function does not see the dynamic environment of the calling process (including error handlers), and cannot be debugged properly. It is also called often, and so it needs to be reasonably fast and not allocate much. In addition, having to call the wait function adds overhead to the system. Therefore in general, if you can achieve the required effect by using either any of the specific wait functions or a `process-wait-local*` function, you should do that and avoid `process-wait` and `process-wait-with-timeout`.

`process-wait-local` and `process-wait-local-with-timeout` do not have all the disadvantages listed above, but their *wait-function* is called only when the process is poked (or at the end of the *timeout*). That means that the programmer does need to worry about when they are called. Typically some other process will set up something, and then poke the waiting process to check if it can run.

Note: if the setting up process always knows for sure whether the waiting process can run, then it is normally simpler to use one of the specific Process Wait functions, or maybe even `process-stop` and `process-unstop`.

The `*-periodic-checks` functions give a partial solution to the question of calling the wait function, by ensuring there is a maximum period of time between calls. If having a bounded delay where a bound of more than 0.1 second is not a problem, then the `*-periodic-checks` functions are a simple and efficient way to achieve it.

When the delays need to be bounded by a shorter period, either one of the specific Process Wait functions or explicit calls to `process-poke` need to be used. The latter combined with `process-wait-local` is the most efficient mechanism, but it does require the programmer to ensure that `process-poke` is called in all the right places.

15.5.3 Communication between processes and synchronization

The simplest way to pass a specific event between two processes is to use `process-wait-for-event` on the receiving process, and `process-send` on the sender side. The "event" that is passed is can be any Lisp object.

`process-send` and `process-wait-for-event` use a `mp:mailbox` to pass the object (the `process-mailbox` of the receiver). It is possible to use a `mp:mailbox` object directly, and to communicate between multiple senders and receivers. Use `make-mailbox` to make a mailbox, and `mailbox-send` to put a message in it. The receiver(s) use either `mailbox-wait-for-event` and `mailbox-read`.

`mailbox-wait-for-event` should be used on processes that may make windows (including any process associated with a CAPI interface), but can be used elsewhere. `mailbox-read` is faster, but if it used on a process with a window it may cause hanging.

`process-wait-for-event` and `process-send` and `mp:mailbox` are the primary interface for communication between processes, and should be used unless there is a very good reason to use a different mechanism.

15.5.4 Synchronization

Synchronization can be achieved by the various `process-wait*` functions with the appropriate *wait-function* argument, but for simple cases of synchronization it is better to use the synchronization objects: condition variables or barriers. These synchronization objects are simple, efficient, deal with all thread safety issues, and ensure that the processes that are ready to run will run immediately, rather than the next time that the wait function is called.

Condition variables are used when one or more processes have the knowledge to control when another process(es) runs. The "ignorant" process(es) use `condition-variable-wait` to wait until they can continue. The "knowledgable" process(es) use `condition-variable-signal` and `condition-variable-broadcast` to tell the "ignorant" processes when they can run. Because the communication is via the condition variable, the processes do not need to know explicitly about each other. For more details, see "Condition variables" on page 186.

Barriers are used (mainly) for symmetric synchronization, when a group of processes needs to ensure that none of them goes too far ahead of the rest. The processes call `barrier-wait` when they want to synchronize, and `barrier-wait` waits until the other process arrive too (that is, they call `barrier-wait`). Barriers have additional features that allow more complex synchronization. For more details, see "Synchronization barriers" on page 187.

15.6 Synchronization between threads

In LispWorks 5.1 and previous versions, the main way to synchronize between threads is to use `mp:process-wait` or `mp:process-wait-with-timeout` to supply a predicate to the scheduler. The predicate runs periodically in the background to identify threads that are no longer blocked.

These functions are still available, but there are some alternatives that can be more efficient in many cases by removing the need for the scheduler. The alternatives are:

- Mailboxes (FIFO queues). See `make-mailbox` and `mailbox-send`.
- Condition Variables (used with a lock). See “Condition variables” on page 186.
- Barriers (counting arrivals at a certain point in the code). See “Synchronization barriers” on page 187.
- Counting Semaphores (limiting the number of users of a shared resource). See “Counting semaphores” on page 188

Access to all of these objects is atomic and does not require additional locks (except for the lock that is already used with a condition variable).

15.6.1 Condition variables

A condition variable allows you to wait for some condition to be satisfied, based on the values stored in shared data that is protected by a lock. The condition is typically something like data becoming available in a queue.

The function `condition-variable-wait` is used to wait for a condition variable to be signalled. It is always called with the lock held, which is automatically released while waiting and reclaimed before continuing. More than one thread can wait for a particular condition variable, so after being notified about the condition changing, you should check the shared data to see if it represents a useful state and call `condition-variable-wait` again if not.

The function `condition-variable-signal` is used to wake exactly one thread that is waiting for the condition variable. If no threads are waiting, then nothing happens.

Alternatively, the function `condition-variable-broadcast` can be used to wake all of the threads that are waiting at the time it is called.

Any threads that wait after the call to `condition-variable-signal` or `condition-variable-broadcast` will not be woken until the next call.

In most uses of condition variables, the call to `condition-variable-signal` or `condition-variable-broadcast` should be made while holding the lock that was used when calling `condition-variable-wait` for this condition variable. This ensures that the signal is not lost if another thread is just about to call `condition-variable-wait`.

The function `condition-variable-wait-count` can be used to determine the current number of threads waiting for a condition variable.

The condition variable implementation in LispWorks aims to comply with the POSIX standard where possible.

`condition-variable-wait`, `condition-variable-signal` and `condition-variable-broadcast` have corresponding functions `lock-and-condition-variable-wait`, `lock-and-condition-variable-signal` and `lock-and-condition-variable-broadcast`. For `condition-variable-wait` there is also `simple-lock-and-condition-variable-wait`, which is simpler to use. The `lock-and-condition-*` functions perform the equivalent of locking and in the scope of the lock doing something and calling the corresponding `condition-*` function.

The `lock-and-condition-*` functions not only make it simpler to code, they also make it easier to avoid mistakes, and can optimize some cases (in particular, the quite common case when there is no need to lock on exit from `condition-variable-wait`). They are the recommended interface.

The `lock-and-condition-*` functions can be used together with `condition-*` functions on the same locks and condition variables.

Note: In cases when only one process waits for the condition, using `process-wait-local` for waiting and `process-poke` for signalling is easier, and involves less overhead.

15.6.2 Synchronization barriers

Barriers are objects that are used to synchronize multiple threads. A barrier has a `count` that determines how many "arrivals" (calls to `barrier-wait`) have to occur before these calls return.

The main usage of barriers is to ensure that a group of threads have all finished some stage of an algorithm before any of them proceeds.

The typical way of using a barrier is to make one with a `count` that is the same as the number of threads that are going to work in parallel and then create the threads to do the work. When each thread has done its work, it synchronizes with the others by calling `barrier-wait`. In most cases `barrier-wait` is the only barrier API that is used.

For example, assume you have a task that be broken into two stages, where each stage can be done in parallel by several threads, but the first stage must be completely finished before any processing of the second stage can start. Then the code will do:

```
(let ((barrier (mp:make-barrier num-of-processes)))
  (dotimes (p num-of-processes)
    (mp:process-run-function (format nil "Task worker ~d" p)
      ()
      #'(lambda (process-number barrier)
          (do-first-stage process-number)
          (mp:barrier-wait barrier)
          (do-second-stage process-number))
      p
      barrier)))
```

It is also possible to use the barrier to block an indefinite number (up to `most-positive-fixnum`) of processes, until another process decides that they can go. For this the barrier is made with `count t` (or `most-positive-fixnum`). The other process then uses `barrier-disable` to "open" the barrier. If required, the barrier can be enabled again by `barrier-enable`.

See also `barrier-block-and-wait`.

15.6.3 Counting semaphores

A counting semaphore is a synchronization object that allows different threads to coordinate their use of a shared resource that contains some number of available units. The meaning of each unit depends on what the semaphore is being used to synchronize.

The three main functions associated with semaphores are: `make-semaphore`, which makes a new semaphore object; `semaphore-acquire`, which acquires units from a semaphore and `semaphore-release`, which releases units back to a semaphore. The current thread will block if it attempts to acquire more units than are current available.

The functions `semaphore-name`, `semaphore-count` and `semaphore-wait-count` can be used to query the name, available unit count and count of waiting units from a semaphore.

15.7 Timers

Use timers to run code after a specified time has passed. You can schedule a timer to run once or repeat at regular intervals, and you can unschedule it before it expires.

For the details, see the reference entries for `make-timer` and `schedule-timer`.

15.7.1 Timers and multiprocessing

Timers run in unpredictable threads, therefore it is not safe to run code that interacts with the user directly. The recommended solution is something like

```
(mp:schedule-timer-relative
  (mp:make-timer 'capi:execute-with-interface
    interface
    'capi:display-message "Time's up")
  5)
```

or

```
(mp:schedule-timer
  (mp:make-timer 'capi:execute-with-interface
    interface
    'capi:display-message "Lunchtime")
  (* 4 60 60))
```

where `interface` is an existing CAPI interface on the screen.

Timers actually run in the process that is current when the scheduled time is reached. This is likely to be The Idle Process in cases where LispWorks is sleeping, but it is inherently unpredictable.

15.7.2 Input and output for timer functions

I/O streams default to the standard input and output of the process, which is initially `*terminal-io*` in the case of The Idle Process.

15.8 Process properties

A "process property" is a pair of an indicator and a value that is associated with it for a process.

LispWorks has two kinds of process properties: general and private. These two kinds of properties are stored separately, and the association of indicator/value in each property kind is independent of any in the other property kind.

General properties are stored in the process plist, and can be modified from other processes.

Private properties can only be modified by the current process. Private properties are faster to modify, because the modification does not need to be thread-safe.

Otherwise there is little difference between general and private properties.

`process-plist` and `(setf process-plist)` are not thread safe. In LispWorks 5.1 and earlier the only interface to process properties is `process-plist`, but this does not work well in SMP LispWorks, and so it is deprecated.

There is no parallel to `process-plist` for the private properties.

The general properties are accessed by: `process-property`, `(setf process-property)`, `remove-process-property`, `pushnew-to-process-property` and `remove-from-process-property`.

The private properties are accessed by: `get-process-private-property` (access from other processes), `process-private-property`, `(setf process-private-property)`, `remove-process-private-property`, `pushnew-to-process-private-property` and `remove-from-process-private-property`.

15.9 Native threads and foreign code

Support for native threads differs between platforms as described in this section.

15.9.1 Native threads on Windows, Mac OS X, Linux, x86/x64 Solaris and FreeBSD

Each Lisp `mp:process` has a separate native thread and in LispWorks 6.0 and later versions these threads can run simultaneously.

Note: In LispWorks 5.1 and earlier versions, you can have many runnable `mp:process` objects/native threads, but Lisp code can only run in one thread

at a time and a lock is used to enforce this. This can limit performance on a computer with multiple CPU cores. When a foreign function is called using the FLI, the lock is released until the function returns. This allows other Lisp threads to run, for instance while waiting for a database query to execute.

You can call back into Lisp using `fli:define-foreign-callable` in any thread, without any other setup.

Note: In a LispWorks 5.0 executable on Microsoft Windows you must first call `setup-for-alien-threads` before calling back into Lisp, but in LispWorks 5.1 and later versions this setup is handled automatically (and `setup-for-alien-threads` does not exist).

Threads running Lisp code can be rescheduled preemptively, so if you call into Lisp from more than one thread simultaneously and one request takes a long time then it will not delay the requests in other threads.

15.9.2 Native threads on other platforms

Lisp uses a single native thread and implements user level threads to support `mp:process`.

You can only call back into Lisp from its single native thread.

Note: This section applies to LispWorks for UNIX only (not LispWorks for Linux, FreeBSD, x86/x64 Solaris or Macintosh).

15.9.3 Foreign callbacks on threads not created by Lisp

If a foreign callback occurs on a thread that was not created by LispWorks, then some data is kept on the Lisp side to make the foreign callback entry faster next time. This data is removed when the thread dies, but you force it to be removed sooner by calling `last-callback-on-thread`.

15.10 Low level atomic operations

Low level atomic operations are defined in all cases for a specific set of places. These places are listed in Table 15.1:

Table 15.1 Places for low-level atomic operations

Place	Notes
<code>(symbol-value symbol)</code>	When <i>symbol</i> is dynamically bound, this means the dynamically bound value.
A dynamically bound <i>symbol</i>	The dynamically bound value.
A lexically bound <i>symbol</i>	It is an error to use a low level atomic operation on a lexically bound symbol.
<code>(car cons)</code>	
<code>(cdr cons)</code>	
<code>(the type place)</code>	For another <i>place</i> listed in this table.
<code>(svref sv index)</code>	Only <code>simple-vector</code> .
Structure accessors	The structure must be defined at compile time.
<code>(slot-value object slot-name)</code>	See below.

Notes about atomic `slot-value` operations:

1. They ignore the MOP `slot-value-using-class` protocol and can only be used for `:instance` and `:class` allocated slots.
2. They are slower than the atomic operations on other types of object because they have to lock the instance. Normally it would be better to have a slot pointing to some other object (for example a structure) and do the atomic operations on that object.

The low level atomic operations implicitly ensure order of memory between operations in different threads.

The low level atomic operations are: `atomic-push`, `atomic-pop`, `atomic-fixnum-incf`, `atomic-fixnum-decf`, `atomic-incf`, `atomic-decf`, `atomic-exchange` and `compare-and-swap`.

Application of macros that are defined by `define-atomic-modify-macro` is also restricted to the places in Table 15.1 above, because they implicitly use low level atomic operations.

You can test whether a place is suitable for use with these operations by the predicate `low-level-atomic-place-p`.

15.10.1 Aids for implementing modification checks

The macros `with-modification-check-macro` and `with-modification-change` provide a way for a body of code to execute and check whether there was any "modification" during this execution, where modification is execution of some other piece of code. This is useful in situations when reading some data out of some data structure is more common than modification, and reading the data involves getting some values that need to be consistent. It makes it possible to ensure consistency of the values without a lock.

The checking code should be wrapped by the macro `with-modification-check-macro`, and the modifying code should be wrapped by the macro `with-modification-change`. They are associated by the fact that their `modification-place` argument is the same.

`modification-place` is a place as defined in Common Lisp (it does not need to be one of the places for atomic locking) which can receive a fixnum. It must be initialized to a fixnum. It must not be modified by any code except `with-modification-change`.

`with-modification-check-macro` defines a lexical macro (by `macrolet`) with the name `macro-name` which takes no arguments, and is used to check if there was any change since the entering the body.

Note that these macros do not guard against errors that may occur because of changes to the data structures that are accessed, and do not create any locking between users of these macro. In particular, the modifying code will typically

need to lock something too, and the checking code must do only operations that cannot fail because of modification in another thread.

15.10.1.1 Example modification check

```
(defstruct my-cache
  (modification-count 0)
  a
  b)

;; modifier code
(sys:with-modification-change
 (my-cache-modification-count cache)
 (setf (my-cache-a cache) (calculate-a-value ....)
       (my-cache-b cache) (calculate-b-value ....)))

;; reading code
(loop
  (sys:with-modification-check-macro
    my-cache-did-not-change-p (my-cache-modification-count cache)
    (let ((a (my-cache-a cache))
          (b (my-cache-b cache)))
      (when (my-cache-did-not-change-p)
        (return (values a b)))))
```

Provided that all modification to the `a` and `b` slots of a `my-cache` object are done by the modifier code above, the return values of `a` and `b` in the reading code are guaranteed to have been set by the same `setf` invocation in the modifier code.

15.10.2 Ensuring order of memory between operations in different threads

A set of synchronization functions is provided which ensure order of memory between operations in different threads. These are `ensure-loads-after-loads`, `ensure-memory-after-store`, `ensure-stores-after-memory` and `ensure-stores-after-stores`.

Note: You should have a good understanding of multiprocessing issues at the CPU level to write code that actually needs these functions.

The effect of each of these functions is to ensure that all the operations of the first type (the word following the `ensure-`) that are in the program after the call to the function are executed after all the operations of the second type (last

word in the function name) that are in the program before the call to the function.

Before or after "in the program" means the order that a programmer interpreting (correctly) the program would expect the operations to be executed. On a modern CPU this is not necessarily the same as the actual execution order. On a single CPU the end result is guaranteed to be the same, but on a computer with multiple CPU cores it is not.

An operation of type *load* is an operation that reads data from an object into a local variable. Typical *load* operations are `car`, `cdr`, `svref`, structure accessors, `slot-value` and getting the value of a symbol. A *store* operation is an operation that modifies data in an object. A *memory* operation is either a *load* or a *store*.

You need these functions when you need to synchronize between threads and you do not want to use the system supplied synchronization objects ("Locks", mailboxes, "Condition variables", "Counting semaphores", "Synchronization barriers"). In most cases you should try first to use a synchronization object. Using the synchronization functions described in this section is useful if you can identify a serious bottleneck in your code that can be optimized using them.

For simple cases you should consider whether `with-modification-check-macro` and `with-modification-change` gives you the functionality you need.

15.10.2.1 Example of ensuring order of memory

Suppose you have two code fragments, which may end up executed in parallel, and both of which access a global structure `*gs*`. The first fragment is a setter, and you can be sure that it is not executed in parallel to itself (normally because it actually runs inside a lock):

```
(setf
  (my-structure-value-slot *gs*)    ; store1
  some-value)
(setf
  (my-structure-counter-slot *gs*) ; store2
  counter)
```

The second fragment is the reader. You want to guarantee that it gets a value that was stored after the counter reached some value (the counter value always increases). You may think that this will suffice:

```
(if (>=
      (my-structure-counter-slot *gs*) ; load1
      counter)
    (my-structure-value-slot *gs*)      ; load2
  (.. something else ...))
```

Programmatically, if the `>=` is true then `store2` already occurred before `load1`, therefore `store1` also occurred before `load1`, and `load2` which happens after `load1` must happen after `store1`.

On a single CPU that is true. On a computer with multiple CPU cores it can go wrong (that is, `load2` can happen before `store1`) because of two possible reasons:

1. `load2` may happen before `load1`.
2. `store2` may happen before `store1`.

To guarantee that `load2` happens after `store1`, both of these possibilities need to be dealt with. Thus the setter has to be:

```
(setf (my-structure-value-slot *gs*)      ; store1
      some-value)
(sys:ensure-stores-after-stores)        ; ensure store order
(setf (my-structure-counter-slot *gs*) ; store2
      (incf-counter))
```

and the reader has to be:

```
(if (> (my-structure-counter-slot *gs*) ; load1
        my-counter)
  (progn
    (sys:ensure-loads-after-loads)      ; ensure load order
    (my-structure-value-slot *gs*))     ; load2
  (.. something else ...))
```

Note that somehow both threads know about `counter`, and normally will have to synchronize the getting of its value too.

16

Common Defsystem and ASDF

This chapter describes tools for managing programs comprising many source files. Most of the material concerns LispWorks' native `defsystem` ("Common Defsystem"), but the last section describes how to use the popular open source alternative ASDF with LispWorks.

16.1 Introduction

When an application becomes large, it is usually prudent to divide its source into separate files. This makes the individual parts of the program easier to find and speeds up editing and compiling. When you make a small change to one file, just recompiling that file may be all that is necessary to bring the whole program up to date.

The drawback of this approach is that it is difficult to keep track of many separate files of source code. If you want to load the whole program from scratch, you need to load several files, which is tedious to do manually, as well as prone to error. Similarly, if you wish to recompile the whole program, you must check every file in the program to see if the source file is out of date with respect to the object file, and if so re-compile it.

To make matters more complicated, files often have interdependencies; files containing macros must be loaded before files that use them are compiled. Similarly, compilation of one file may necessitate the compilation of another

file even if its object file is not out of date. Furthermore, one application may consist of files of more than one source code language, for example Lisp files and C files. This means that different compilation and loading mechanisms are required.

The LispWorks system tools, and the System Browser in the LispWorks IDE, are designed to take care of these problems, allowing consistent development and maintenance of large programs spread over many files. A system is basically a collection of files that together constitute a program (or a part of a program), plus rules expressing any interdependencies which exist between these files.

You can define a system in your source code using the `defsystem` macro. Once defined, operations such as loading, compiling and printing can be performed on the system as a whole. The system tools ensure that these operations are carried out completely and consistently, without doing unnecessary work. A system may itself have other systems as members, allowing a program to consist of a hierarchy of systems. Each system is treated independently of the others, and can be used to collect related pieces of code within the overall program. Operations on higher-level systems are invoked recursively on member systems.

It is also possible to define a system in your code using `asdf:defsystem`, an open source system definition utility with similar functionality to LispWorks `defsystem`. See “Using ASDF” on page 203 for a description of how to use ASDF with LispWorks.

16.2 Defining a system

A system is defined with a `defsystem` form in an ordinary Lisp source file. This form must be loaded into the Lisp image in order to define the system in the environment. Once loaded, operations can be carried out on the system by invoking Lisp functions, or, more conveniently, by using the system browser.

For example, the expression:

```
CL-USER 5 > (compile-system 'debug-app :force t)
```

would compile every file in a system called `debug-app`.

Note: When defining a hierarchy of systems, the leaf systems must be defined first — that is, a system must be declared before any systems that include it.

By convention, system definitions are placed in a file called `defsys.lisp` which usually resides in the same directory as the members of the system.

The full syntax is given in `defsystem`, page 725. Below is a brief introduction.

16.2.1 DEFSYSTEM syntax

`defsystem` *Macro*

`defsystem system-name options &key members rules`

system-name A symbol used as the name of the system. If a string is given, it is interned in the current package.

options Any of a number of options that can be specified.

members The members of the system. These may be files of Common Lisp source code, foreign source code, or other systems.

rules A set of rules describing the requirements for and order in which compilation and loading of the system members should take place.

See the following sections for more information about these parameters.

16.2.2 DEFSYSTEM options

Options may be specified to `defsystem` which affect the behavior of the system as a whole. For example, `:package` specifies a default package into which files in the system are compiled and loaded if the file itself does not contain its own package declaration. The `:default-pathname` option tells the system tools where to find files which are not expressed as a full pathname.

16.2.3 DEFSYSTEM members

The `:members` keyword to `defsystem` is used to specify the members of a system. The argument given to `:members` is a list of strings. A system member is

either a file or another system, identified by a name. If a full pathname is given then the function `pathname-name` is used to identify the name of the member. Thus, for example, the name of a member expressed as
`/u/neald/foo.lisp` is `foo`.

System members must have unique names, by a case-insensitive string comparison, so if a system has a member called "`foo`" then it cannot have another member (a file or a system) named "`foo`", "`FOO`" or `foo`.

The behavior of any member within a system can be constrained by supplying keyword arguments to the member itself. So, for example, specifying the `:source-only` keyword ensures that only the source file for that member is ever loaded.

16.2.4 DEFSYSTEM rules

Rules may be defined in a system which modify the default behavior of that system, ensuring, for instance, that certain files are always loaded or compiled before others.

Rules apply to files and subsystems alike as members of their parent system, but are not inherited by subsystems.

When you invoke an action such as compiling a system, the following happens by default:

- Each member of the system is considered in turn, in the order they are given in the system definition.
- If the member is itself a system then the action is performed on that system too, and so on recursively.
- If the member is a file and action-specific constraints are satisfied, the file action is inserted into a *plan*.

For example, in the case of compiling, a “compile this file” event is put into the plan if the source file is newer than the object file.

- After the plan has been assembled, it can be viewed or executed.

This behavior can be modified by describing dependencies between the members using *rules*. These are specified using the `:rules` keyword to `defsystem`.

A rule has three components:

The target(s).	The action that is performed if the rule executes successfully.
	This is an action-member description like <code>:compile "foo"</code> . The member can be an actual member of the system or <code>:all</code> (meaning the rule should apply to each member of the system).

The actions that the target(s) are `:caused-by`.

The actions that cause the rule to execute successfully.

This is a list of action-member descriptions. The member of each of these descriptions should be either a real system member, or `:previous`, which means all members listed before the member of the target in the system description.

If any of these descriptions are already in the current plan (as a result of other rules executing successfully, or as a result of default system behavior), they trigger successful execution of this rule.

The actions that the target(s) `:requires`.

The actions that need to be performed before the rule can execute successfully.

This is a list of action-member descriptions that should be planned for before the action on the target(s). Again, each member should either be a real member of the system, or `:previous`.

The use of the keyword `:previous` means, for example, that you can specify that in order to compile a file in the system, all the members that come before it must be loaded.

When the action and member of a target are matched during the traversal of the list of members, the target is inserted into the plan if either of the following are true:

- any of the action-member descriptions in the `:caused-by` clause is already in the plan, or

- any implicit conditions (such as the source file being newer than the object file) are satisfied.

If the target is put into the plan then other targets are inserted beforehand if the action-member description of any `:requires` clause is not already in the plan.

16.2.5 Examples

Consider an example system, `demo`, defined as follows:

```
(defsystem demo (:package "USER")
  :members ("parent"
            "child1"
            "child2")
  :rules ((:in-order-to :compile ("child1" "child2"))
           (:caused-by (:compile "parent")))
           (:requires (:load "parent"))))
```

This system compiles and loads members into the `USER` package if the members themselves do not specify packages. The system contains three members — `parent`, `child1`, and `child2` — which may themselves be either files or other systems. There is only one explicit rule in the example. If `parent` needs to be compiled (for instance, if it has been changed), then this causes `child1` and `child2` to be compiled as well, irrespective of whether they have themselves changed. In order for them to be compiled, `parent` must first be loaded.

Implicitly, it is always the case that if any member changes, it needs to be compiled when you compile the system. The explicit rule above means that if the changed member happens to be `parent`, then every member gets compiled. If the changed member is not `parent`, then `parent` must at least be loaded before compiling takes place.

The next example shows a system consisting of three files:

```
(defsystem my-system
  (:default-pathname "~/junk/")
  :members ("a" "b" "c")
  :rules ((:in-order-to :compile ("c"))
           (:requires (:load "a")))
           (:caused-by (:compile "b"))))
```

What plan is produced when all three files have already been compiled, but the file `b.lisp` has since been changed?

First, file `a.lisp` is considered. This file has already been compiled, so no instructions are added to the plan.

Second, file `b.lisp` is considered. Since this file has changed, the instruction `compile b` is added to the plan.

Finally file `c.lisp` is considered. Although this has already been compiled, the clause

```
(:caused-by (:compile "b"))
```

causes the instruction `compile c` to be added to the plan. The compilation of `c.lisp` also requires that `a.lisp` is loaded, so the instruction `load a` is added to the plan first. This gives us the following plan:

1. Compile `b.lisp`.
2. Load `a.lisp`.
3. Compile `c.lisp`.

This last example shows how to make each fasl get loaded immediately after compiling it:

```
(defsystem my-system ()
  :members ("foo" "bar" "baz" "quux")
  :rules ((:in-order-to :compile :all
    (:requires (:load :previous)))))

(compile-system my-system :load t)
```

16.3 Using ASDF

You can load the supplied version of ASDF 2 by

```
(require "asdf")
```

Optionally, if you actually want your later version of ASDF 2, do

```
(asdf:load-system :asdf)
```

You may need to configure ASDF. For the language-level interface you should follow the ASDF documentation at <http://common-lisp.net/project/asdf/>.

Then load your ASDF system definitions and you are ready to work with ASDF systems in LispWorks.

It is possible to work with both Common Defsystem and ASDF in the same LispWorks image, as long as you use the appropriate APIs to operate on each type of system.

16.3.1 Bypassing the supplied version of ASDF

To use a specific version of ASDF 2 without loading the version supplied with LispWorks, you should load it directly and then call

```
(provide "asdf")
```

to prevent the distributed version from being loaded later.

16.3.2 Using ASDF in the LispWorks IDE

You can work with your ASDF systems using the LispWorks IDE tools.

This needs some integration code which makes the System Browser, Editor and Search Files tools work with ASDF systems as well as 'native' LispWorks systems. The ASDF integration code is in

```
examples/misc/asdf-integration.lisp
```

in the LispWorks library and if necessary you can load it directly. However, it is more convenient to rely on this code being loaded automatically.

The variable `*autoload-asdf-integration*` is consulted when the LispWorks IDE starts. If its value is true (this is the default) then the ASDF integration code is loaded automatically when ASDF is loaded.

See the comments in `asdf-integration.lisp` for more information about using ASDF with LispWorks.

17

The Parser Generator

17.1 Introduction

The parser generator generates an LALR parser from a specification of a grammar. The parser generator has a simple facility for the static resolution of ambiguity in the grammar and supports an automatic run-time error correction mechanism as well as user-defined error correction. Semantic actions can be included in the rules for the grammar by specifying Lisp forms to be evaluated when reductions are performed.

For further details on LALR parsing, see *Compilers, Principles Techniques and Tools*, by Aho, Sethi and Ullman, publishers Addison Wesley, 1986.

Load the parser generator by (`(require "parsergen")`).

17.2 Grammar rules

The parser generator is accessed by the macro `defparser`, described below:

`defparser` *Macro*

```
defparser name {rules}*
```

<i>name</i>	The name to be used for the parsing function. The remainder of the macro form specifies the reduction rules and semantic actions for the grammar.
<i>rules</i>	The rules specified in a <code>defparser</code> form are of two types, <i>normal rules</i> and <i>error rules</i> , described below.

Each *normal rule* corresponds to one production of the grammar to be parsed:

```
( (non-terminal {grammar-symbol}* ) {form}* )
```

The *non-terminal* is the left-hand side of the grammar production and the list of grammar symbols defines the right-hand side of the production. (The right-hand side may be empty.) The list of forms specifies the semantic action to be taken when the reduction is made by the parser. These forms may contain references to the variables `$1 ... $n`, where *n* is the length of the right hand side of the production. When the reduction is done, these variables are bound to the semantic values corresponding to the grammar symbols of the rule.

17.2.1 Example

If a grammar contains the production:

```
expression -> expression operator expression
```

with a semantic representation of a list of the individual semantic values, the Lisp grammar would contain the rule:

```
( (expression expression operator expression) (list $1 $2 $3) )
```

Error productions of the form:

```
( (nt :error) (some error behavior) )
```

are explained in the section below.

The first rule of the grammar should be of the form:

```
( (nt nt1) $1)
```

where the non-terminal *nt* has no other productions and *nt1* serves as the main “top-level” non-terminal.

17.2.2 Resolving ambiguities

If the grammar is ambiguous, there is conflict between rules of the grammar: either between reducing with two different rules or between reducing by a rule and shifting an input symbol. Such a conflict is resolved at parser generation time by selecting the highest priority action, where the priority of a reduce action is determined by the closeness of the rule to the beginning of the grammar. A priority is assigned to a shift by associating it with the rule that results in the shift being performed.

For example, if the grammar contains the two rules:

- Rule a: *statement* -> `:if expression :then statement :else statement`
- Rule b: *statement* -> `:if expression :then statement`

this results in a conflict in the parser between a shift of `:else`, for rule a, and a reduce by rule b. This conflict may be resolved by listing rule a earlier in the grammar than rule b. This ensures that the shift is always done.

Note that ambiguities cannot always be resolved successfully in this way. In this example, if the ambiguity is resolved the other way around, by listing rule b first, this results in the `if ... then ...` part of an `if ... then ... else ...` statement being reduced, and a syntax error is produced for the `else` part.

During parser generation, any conflicts between rules are reported, together with information about how the conflict was resolved.

17.3 Functions defined by defparser

The form `(defparser name grammar)` defines a number of functions. The main function *name* is defined as the parsing function. For example:

```
(defparser my-parser .. grammar .. )
```

defines the function

```
my-parser lexer &optional symbol-to-string =>
```

lexer specifies the lexical analyzer function to be used. The optional argument *symbol-to-string* should be a function mapping grammar symbols to strings for printing purposes. The default value of *symbol-to-string* is the function `cl:identity`.

`defparser` also defines functions corresponding to the individual actions of the parser.

Normal actions are named:

`name-actionindex`

and error actions are named:

`name-error-actionindex`

where `name` here is the name as given to `defparser` and `index` is the number of the rule or error rule in the grammar.

All function names are interned in the current package when `defparser` is called.

17.4 Error handling

The parser supports automatic error correction of its input. The strategy used involves attempting to either push a new token onto the input, replacing an erroneous symbol, or discarding an erroneous symbol. Such action is only taken if it is guaranteed that the parser can continue parsing and read at least one more symbol from its input.

If the correction strategy fails, then error recovery is invoked.

The parser allows the inclusion of grammar productions of the form:

`non-terminal -> :error`

This means that the parser accepts an erroneous string of tokens as constituting an occurrence of the non-terminal. Such productions may be used to skip over portions of input when attempting to recover from an error. The action associated with such an error is specified by a form in the same way as for ordinary actions. The action may perform manipulation of the parser state and input.

17.5 Interface to lexical analyzer

The lexical analyzer function that is passed to the parser is expected to be a function of zero arguments that returns two values each time it is called. The first value is the next token on the input and the second value is the semantic

value corresponding to that token. If there is no more input, then the lexical analyzer may return either the token :eoi or nil.

For example:

```
(defparser my-parser
  ...)

(defun my-lexer (stream)
  .. read next token from stream ..
  (values token value))
(defun my-symbol-to-string (symbol)
  .. returns a string ..)
(defun my-parse-stream (stream)
  (let ((lexer #'(lambda () (my-lexer stream))))
    (my-parser lexer #'my-symbol-to-string)))
```

Note that during error correction, the parser may push extra tokens onto the input, in which case they are given the semantic value nil. The semantic actions should therefore be capable of dealing with this situation. Manipulation of the input (for example pushing extra tokens) is done within the parser generator and the lexical analyzer need not concern itself with this.

17.6 Example

The following example shows a simple grammar for a very small subset of English.

```

(defpackage "ENGLISH-PARSER")
(in-package "ENGLISH-PARSER")
(use-package '(parsergen))

;; Define the parser itself.

(defparser english-parser
  ((bs s) $1)
  ((s np vp)
   `($1 ,$2))
  ((bnp :adj bnp)
   `($1 ,$2))
  ((bnp bnp relp)
   `($1 ,$2))
  ((bnp :noun) $1)
  ((relp :rel vp)
   `($1 ,$2))
  ((vp :verb np locp)
   `($1 ,$2 ,$3))
  ((vp :verb locp)
   `($1 ,$2))
  ((vp :verb np)
   `($1 ,$2))
  ((vp :verb)
   $1)
  ((np :art bnp locp)
   `($1 ,$2 ,$3))
  ((np :art bnp)
   `($1 ,$2))
  ((np bnp) $1)
  ((locp :loc np)
   `($1 ,$2)))

;; The lexer function.

;; The basic lexing function

(defvar *input*)
(defun lex-english ()
  (let ((symbol (pop *input*)))
    (if symbol (get-lex-class symbol)
        nil)))

;; Getting syntactic categories.

(defparameter *words*
  '("the" "a" "some" "art" "ate" "verb" "hit"))

```

```
(cat :noun) (rat :noun) (mat :noun) (which :rel) (that :rel)
(who :rel) (man :noun) (big :adj) (small :adj) (brown :adj)
(dog :noun) (on :loc) (with :loc) (behind :loc) (door :noun)
(sat :verb) (floor :noun)))
```

```
(defun get-lex-class (word)
  (values
    (or (cadr (assoc word *words*))
        :unknown)
    word))
```

```
;;; The main function -- note bindings of globals (these
;;; are exported from the parsergen package).
```

```
(defun parse-english (input)
  (let ((*input* input))
    (english-parser #'lex-english)))
```

The following example session shows the parsing of some sentences.

```
ENGLISH-PARSER 34 > (parse-english '(the cat sat on the
                                      mat))
((THE CAT) (SAT (ON (THE MAT))))
```

```
ENGLISH-PARSER 35 > (parse-english '(the big brown dog
                                      behind the door ate the cat
                                      which sat on the floor))
((THE (BIG (BROWN DOG)) (BEHIND (THE DOOR)))
 (ATE (THE (CAT (WHICH (SAT (ON (THE FLOOR))))))))
```

18

Dynamic Data Exchange

18.1 Introduction

Dynamic data exchange (DDE) involves passing data and instructions between applications running under the Microsoft Windows operating system. Typically the data is passed in the form of a string, which is interpreted when it is received. One application acts as a *server* and the other as a *client*.

18.1.1 Types of transaction

The server is normally a passive object, which waits for a client object to tell it what to do. The client can communicate with the server in four ways:

- The client can issue a *request transaction* to the server. This means the client is asking for some information about the server application.
- The client can issue a *poke transaction*. This means the client is passing data to be stored by the server application.
- The client can issue an *execute transaction*. This means the client is asking the server to get the server application to run a command.
- The client can ask the service to set up an *advise loop*, or to close an existing advise loop. An advise loop causes the server to communicate with the client whenever a specified change occurs in the server application.

18.1.2 Conversations, servers, topics, and items

For a transaction to take place between a client and a server, a conversation must be established. A conversation is established when a client makes a request by broadcasting a service name and topic name, and a server responds. Transactions can then take place across the conversation. When no more transactions are to be made, the conversation is terminated.

The following list identifies the elements involved with client/server activity:

conversation	A conversation is established when a server responds to a client.
service name	A service name is a string broadcast by a client hoping to establish a conversation with a server that recognizes the service name. The service name is usually clearly related to the server application name.
topic name	The topic name identifies what the conversation between client and server is to be about. For example, it could be the name of a file that is open in the server application. Each topic is attached to one particular server. A server can have many topics.
item name	The item usually identifies an element of the file identified by the topic which should be read (in the case of a request) or written to (in the case of a poke). For example, it might refer to a cell in a spreadsheet document.

18.1.3 Advise loops

A DDE advise loop describes a connection back to the application that is used to track changes to a DDE topic. It instructs the server to inform the client when data in the server's application changes. Advise loops are set up across a conversation, and closing the conversation closes the advise loop.

An advise loop is identified by an item and a key. The key is included to allow any number of uniquely identifiable advise loops to be set up on the same server/topic/item combination.

A successfully established advise loop is also known as a link. When a change occurs to item, the link informs the client by causing it to execute a function.

There are two types of link: the warm link which only informs the client that a change to item has occurred, and the hot link which also sends the new data across.

Note: a DDE advise loop is not a loop in the program source code. In particular it should not be confused with the "event loop" which is a loop in source code that processes low level events.

18.1.4 Execute transactions

When a client issues an execute transaction to a server, the command to be executed is transferred as a string. This involves the marshalling of the command and its arguments into a suitable string format. The standard format of such a string is:

```
[command(arg1,arg2,...)]
```

18.2 Client interface

18.2.1 Opening and closing conversations

A LispWorks client can open a conversation by using `dde-connect`, which takes a service designator and a topic designator as its arguments. If successful, a conversation object is returned which can be used to refer to the conversation. Conversations are closed by the LispWorks client at the end of a transaction by using `dde-disconnect`.

Another method for managing conversations uses `with-dde-conversation` to bind a conversation with a server across a body of code. If no conversation is available for `with-dde-conversation`, then one is automatically opened. The code is executed and the conversation is closed after the body of code exits.

18.2.2 Automatically managed conversations

There is an alternative to manually establishing a conversation and then disconnecting it once all transactions between server and client are concluded: the automatically managed conversation. Client functions that end with a * conduct automatically managed conversations.

A function handling an automatically managed conversation takes a service designator and topic designator as two of its arguments, and either automatically establishes a conversation with a server responding to the service designator/topic designator pair, or uses an existing equivalent conversation. For the purpose of brevity, functions conducting automatically managed conversations are only briefly mentioned in this chapter. For the details see `dde-advise-start*`, `dde-advise-stop*`, `dde-execute*`, `dde-execute-command*`, `dde-execute-string*`, `dde-item*`, `dde-poke*` and `dde-request*`.

18.2.3 Advise loops

A LispWorks client can set up an advise loop across a conversation using `dde-advise-start`, which takes a *conversation* (or a *service designator/topic* designator pair in the case of an automatically managed conversation using `dde-advise-start*`), an *item*, and a *key* as its main arguments. The *key* argument defaults to the conversation name, and can be used to distinguish between multiple advise loops established on the same service/topic/item group.

Whenever the data monitored by the advise loop changes, a function is called to inform the client. By default this function is the generic function `dde-client-advise-data`. You can add methods to `dde-client-advise-data` specialized on the *key* or the client conversation class. Alternatively, you can supply a different function in the call to `dde-advise-start`.

Note: a DDE advise loop is not a loop in the program source code. In particular it should not be confused with the "event loop" which is a loop in source code that processes low level events.

18.2.3.1 Example advise loop

The example shows you how to set up an advise loop. The code assumes that `win32` package symbols are visible.

The first step defines a client conversation class, called `my-conv`.

```
(defclass my-conv (dde-client-conversation)
  ())
```

The macro `define-dde-client` can now be used to define a specific instance of the `my-conv` class for referring to a server application that responds to the service name "FOO".

```
(define-dde-client :foo :service "FOO" :class my-conv)
```

The next step defines a method on `dde-client-advise-data` which returns a string stating that the item has changed.

```
(defmethod dde-client-advise-data ((self my-conv) item data &key
  &allow-other-keys)
  (format t "~&Item ~s changed to ~s~%" item data))
```

Finally, the next command starts the advise loop on the server `foo`, with the topic name "`file1`", to monitor the item "`slot1`".

```
(dde-advise-start* :foo "file1" "slot1")
```

When the value of the item specified by "`slot1`" changes, the server calls `dde-client-advise-data` which returns a string, as described above.

The *function* argument of `dde-advise-start` and `dde-advise-start*` specifies the function called by the advise loop when it notices a change to the item it is monitoring. The function is `dde-client-advise-data` by default. A different function can be provided, and should have a lambda list similar to the following:

```
key item data &key conversation &allow-other-keys
```

The arguments *key* and *item* identify the advise loop, or link. The argument *data* contains the new data for hot links; for warm links it is `nil`.

Advise loops are closed using `dde-advise-stop` or `dde-advise-stop*`.

18.2.4 Request and poke transactions

LispWorks clients can issue request and poke transactions across a conversation using `dde-request` and `dde-poke`, which take a *conversation* (or a *service designator/topic* designator pair in the case of an automatically managed conversation), and an *item* as their main arguments. In the case of a poke transaction, data to be poked into *item* must also be provided.

In the case of a successful request transaction with `dde-request` or `dde-request*`, the data contained in *item* is returned to the LispWorks client by the server.

In the case of a successful poke transaction with `dde-poke` or `dde-poke*`, the data provided is poked into *item* by the server.

The accessor `dde-item` (or `dde-item*` for automatically managed conversations) can perform request and poke transactions. It performs a request transaction when read, and a poke transaction when set.

18.2.5 Execute transactions

A client can issue an execute transaction across a conversation, or in the case of an automatically established conversation, to a recognized server. There is no need to specify a topic, as an execute transaction instructs the server application to execute a command.

The command and its arguments are issued to the server in the form of a string in a standard format (see “Execute transactions” on page 215). LispWorks provides two ways of issuing an execute transaction, namely `dde-execute-string` and `dde-execute-command` (and the corresponding * functions that automatically manage conversations).

The following example shows how `dde-execute-string*` can issue a command to a server designated by `:excel` on the topic `:system`, in order to open a file called `foo.xls`:

```
(dde-execute-string* :excel :system "[open(\"foo.xls\")]")
```

The function `dde-execute-command` takes the command to issue, and its arguments, and marshals these into an appropriate string for you. The following example shows how `dde-execute-command*` can issue the same command as in the previous example:

```
(dde-execute-command* :excel :system 'open '("foo.xls"))
```

18.3 Server interface

18.3.1 Starting a DDE server

To provide a LispWorks application with a DDE server, follow the following three steps.

1. Define a specialized Lisp DDE server class using `define-dde-server`. Here the server class is called `foo-server` and it has the service name "FOO":

```
(define-dde-server foo-server "FOO")
```
2. Provide the server class with the functionality it requires by specializing methods on it and/or using `define-dde-server-function`. Here the server function is `bar`, which takes a string as an argument, and prints this to the standard output. For convenience, the system topic is used, though usually it is better to define your own topic.

```
(define-dde-server-function (bar :topic :system)
    :execute
    ((x string))
    (format t "~&~s~%" x)
    t)
```

3. Start an instance of the server `foo-server` using `start-dde-server`.

```
(start-dde-server 'foo-server)
```

This function returns the server object, which responds to requests for conversations with the service name "FOO", and accepts execute transactions for the function `bar` in the "System" topic.

18.3.2 Handling poke and request transactions

Poke and request transactions issued to a server object are handled by defining a method on each of the generic functions `dde-server-poke` and `dde-server-request`.

18.3.3 Topics

DDE servers respond to connection requests containing a service name and a topic name. The service name of a server is the same for any conversation

whereas the topic name may vary from conversation to conversation, and identifies the context of the conversation. Typically, valid topics correspond to open documents within the application, so the set of valid topics varies from time to time. In addition, all servers implement a topic called "`System`", which contains a standard set of items that can be read.

The LispWorks DDE interface supports three types of topics:

- 1. General topics**

A general topic is an instance of a user-defined topic class. The actual set of topics available may vary from time to time as the application is running.

- 2. Dispatching topics**

A dispatching topic has a fixed name, and is available at all times that the server is running. It supports a fixed set of items, and each of these items has Lisp code associated with it to implement these items.

- 3. The system topic.**

The system topic is provided automatically by the LispWorks DDE interface. However, a mechanism is provided to extend the functionality of the system topic by handling additional items.

18.3.3.1 General topics

To use general topics, the LispWorks application must define one or more subclasses of `dde-topic`. If an application supports only a single type of document, it will typically require only one topic class. If several different types of document are supported, it may be convenient to define a different topic class for each type of document.

If the application uses general topics, it should define a method on the `dde-server-topics` generic function, specializing on the application's server class.

18.3.3.2 Dispatching topics

A dispatching topic is a topic which has a fixed name and always exists. Dispatching topics provide dispatching capabilities, whereby appropriate appli-

cation-supplied code is executed for each supported transaction. Dispatch topics are defined using `define-dde-dispatch-topic`.

18.3.3.3 The system topic

The system topic is implemented as a predefined dispatching topic called `:system`. It is automatically available to all defined DDE servers. Its class is `dde-system-topic`, which is a subclass of `dde-topic`.

The following items are implemented by the system topic:

SZDDESYS_ITEM_TOPICS	<i>Constant</i>
-----------------------------	-----------------

The constant `SZDDESYS_ITEM_TOPICS` has the value "`Topics`". Referring to this item in the system topic calls `dde-server-topics` to obtain a list of topics implemented by the server. The server should define a method on this generic function to return a list of strings naming the topics supported by the server. If this item is not to be implemented, do not define a method on the function, or define a method that returns `:unknown`.

SZDDESYS_ITEM_SYSITEMS	<i>Constant</i>
-------------------------------	-----------------

The constant `SZDDESYS_ITEM_SYSITEMS` has the value "`sysItems`". Referring to this item in the system topic calls `dde-topic-items` to obtain a list of items implemented by the system topic. If a server implements additional system topic items it should define a method on the generic function specialized on its server class and `dde-system-topic` returning the complete list of supported topics. The server can return `:unknown` if this item is not to be implemented.

SZDDESYS_ITEM_FORMATS	<i>Constant</i>
------------------------------	-----------------

The constant `SZDDESYS_ITEM_FORMATS` has the value "`Formats`", and returns `unicodetext` and `text`. Currently only text formats are supported.

The system topic is a single object which is used by all DDE servers running in the Lisp image. You should therefore not under normal circumstances modify

it with `define-dde-server-function` by specifying a value of `:system` for the *topic* argument, as this would make the changes to the system topic visible to all users of DDE within the Lisp image.

Instead, specify `:server my-server :topic :system`, where *my-server* is the name of your DDE server. This makes the additional items available only on the system topic of the specified server.

19

Common SQL

This chapter is applicable to UNIX LispWorks and the Enterprise Edition of LispWorks. It describes Common SQL — the LispWorks interface to SQL. It should be used in conjunction with Chapter 38, “The SQL Package”, which contains full reference entries for all the symbols in the SQL package.

For a longer introduction to Common SQL, please see the SQL Tutorial available at www.lispworks.com.

19.1 Introduction

This chapter covers the following areas:

- Initialization and Connection
- The Functional SQL Interface
- The Object-Oriented (CLOS) SQL Interface
- The Symbolic SQL Syntax
- SQL I/O Recording
- SQL Interface Errors

The LispWorks SQL interface uses the following database terminology:

Data Definition Language (DDL)

The language used to specify and interrogate the structure of the database schema.

Data Manipulation Language (DML)

The language used for retrieving and modifying data.
Also known as *query language*.

<i>table</i>	A set of records. Also known as <i>relation</i> .
<i>attribute</i>	A field of information in the table. Also known as <i>column</i> .
<i>record</i>	A complete set of attribute values in the table. Also known as <i>tuple</i> , or <i>row</i> .
<i>view</i>	A display of a table configured to your own needs. Also known as <i>virtual table</i> .

19.1.1 Overview

Common SQL is designed to provide both embedded and transparent access to relational databases from the LispWorks environment. That is, SQL/relational data can be directly manipulated from within Lisp, and also used as necessary when instantiating or accessing particular Lisp objects.

The SQL interface allows the following:

- Direct use of standard SQL statements as strings
- Mixed symbolic SQL and Common Lisp expressions
- Implicit SQL invocation when instantiating or accessing CLOS objects

The SQL interface provides these features through two complementary layers:

- A *functional* SQL interface
- An *object-oriented* SQL interface

The functional interface provides users with Lisp functions which map onto standard SQL DML and DDL commands. Special iteration constructs which utilize these functions are also provided. The object-oriented interface allows users to manipulate database views as CLOS classes via `def-view-class`.

19.1 Introduction

The two interfaces may be flexibly combined in accordance with system requirements and user preference. For example, a *select* query can be used to initialize slots in a CLOS instance; conversely, accessing a CLOS slot may trigger an implicit functional query.

19.1.2 Supported databases

Common SQL supports connections to various databases on the platforms indicated below in Table 19.1. Common SQL may work with other platform/ODBC driver combinations and we would be pleased to hear of your experience with these. The keyword shown in the last column is the corresponding value of the *database-type* argument to `connect`:

Table 19.1 Supported databases

Platform	Database	Driver/Client library	<i>database-type</i>
Windows	ODBC	Microsoft SQL Server	: <code>odbc</code>
Windows	ODBC	Oracle	: <code>odbc</code>
Windows	ODBC	Postgres	: <code>odbc</code>
Linux	ODBC	MySQL	: <code>odbc</code>
Linux	ODBC	Postgres	: <code>odbc</code>
Mac OS X	ODBC	MySQL	: <code>odbc</code>
Mac OS X	ODBC	Postgres	: <code>odbc</code>
Linux	Oracle	Oracle 9i (r2) or 10g	: <code>oracle</code>
Mac OS X/Intel/32-bit	Oracle	Oracle 10g	: <code>oracle</code>
Mac OS X/Intel/64-bit	Oracle	Oracle 10g	: <code>oracle</code>
Mac OS X/PPC/32-bit	Oracle	Oracle 10g	: <code>oracle</code>
Windows	Oracle	Oracle 9i (r2) or 10g	: <code>oracle</code>
Solaris/Intel	Oracle	Oracle 10g	: <code>oracle</code>

Table 19.1 Supported databases

Platform	Database	Driver/Client library	<i>database-type</i>
Solaris/ SPARC	Oracle	Oracle 9i (r2) or 10g	:oracle
HP-UX	Oracle	Oracle 9i (r2) or 10g	:oracle
Linux	Oracle	Oracle	:oracle8
Solaris/ SPARC	Oracle	Oracle	:oracle8
HP-UX	Oracle	Oracle	:oracle8
Linux	PostgreSQL	Postgres	:postgresql
FreeBSD	PostgreSQL	Postgres	:postgresql
Mac OS X	PostgreSQL	Postgres	:postgresql
Windows	PostgreSQL	Postgres	:postgresql
Solaris/Intel	PostgreSQL	Postgres 8.2	:postgresql
Linux	MySQL	MySQL	:mysql
FreeBSD	MySQL	MySQL	:mysql
Mac OS X	MySQL	MySQL	:mysql
Windows	MySQL	MySQL	:mysql
Solaris/Intel	MySQL	MySQL	:mysql
Solaris/ SPARC	MySQL	MySQL	:mysql

Note: MySQL versions prior to 4.1.1 should be run in ANSI mode to work with Common SQL. That is, `mysqld` must be started with `--ansi` or the `ansi` option must appear in the `[mysqld]` section of its configuration file.

Note: To use PostgreSQL on any non-Microsoft Windows platform, LispWorks/Common SQL requires PostgreSQL version $\geq 8.x$ built with `--enable-thread-safety`.

19.2 Initialization

The initialization of Common SQL involves three stages. Firstly the SQL interface loaded. Next, the database type (actually class) to be used is initialized. Finally, Common SQL is used to connect to a database. These stages are explained in more detail in this section.

The Lisp symbols introduced in this chapter are exported from the `sql` package. Application packages requiring convenient access to these facilities should therefore use the `sql` package.

The examples in this chapter assume that the `sql` package is visible.

19.2.1 SQL interface

The SQL interface itself is loaded by issuing the command

`(require "odbc")` or `(require "oracle")` or `(require "postgresql")` or `(require "mysql")`. In an application, this step should be performed at build-time.

Not all of these modules are available on every LispWorks platform. See Table 19.1, page 225 for information about which databases are supported per-platform.

19.2.2 Database classes

A connection to a database is represented by a CLOS instance which holds information about the connected database. The special variable `*default-database*` holds the current connection. The database class is subclassed on both vendor and version to provide the right kind of specialized behavior across database facilities: for example, the transaction model or the “brand” of SQL.

19.2.3 Initialization functions and variables

The initialization of the chosen database type is achieved by calling `initialize-database-type` with the appropriate value of `database-type`. In an application, this step should be done at runtime. Where multiple database types are supported, it is possible to initialize more than one database type if needed (by making multiple calls to `initialize-database-type`).

The following functions and variables are relevant to initialization:

default-database-type specifies the default type of database. The possible values are shown in the *database-type* column of Table 19.1, page 225.

The function **initialize-database-type** initializes a database type according to the value of its *database-type* argument, which defaults to the value of ***default-database-type***.

A sample code sequence for initializing Common SQL to work with an ODBC database, using the above functions and variables, is as follows:

```
(require "odbc")
(setf *default-database-type* :odbc)
(initialize-database-type)
```

You can find which database types have been initialized by the value of the variable ***initialized-database-types***.

19.2.4 Database libraries

Note: This section applies only to Unix/Linux systems.

A database directory environment variable specifies the root of the database directories. This variable is checked by LispWorks when you initialize a database type, and the libraries loaded are dependent on its value. The details of foreign code loading are described in the *LispWorks Foreign Language Interface User Guide and Reference Manual*

Note that most users only need to set the appropriate environment variable for their specific database vendor.

In order to override the default loading of database library code, you may set ***sql-libraries***. To control messages while loading the libraries, set ***sql-loading-verbose***.

In LispWorks for UNIX only (not LispWorks for Linux, x86/x64 Solaris, FreeBSD or Macintosh), the list of library modules is added to **link-load:***default-libraries***** and **read-foreign-modules** is called to do the loading. If you need to load a different set of library modules, add your list of library modules to **link-load:***default-libraries***** before loading.

19.2.5 General database connection and disconnection

Once the database type has been initialized a connection can be established by calling `connect` with an appropriate *connection-spec*. A call to `connect` sets `*default-database*` to the database instance which represents the connection. All the other database functions described take a `:database` argument that can be either a database or a database name, and which defaults to the value of `*default-database*`.

Database connections can be named by passing the `:name` argument to `connect`, allowing you to have more than one connection to a given database. If this is omitted, then a unique database name is constructed from *connection-spec* and a counter. Connection names are compared with `equalp`.

To find all the database connection instances, call the function `connected-databases`. To retrieve the *name* for a connection instance, call `database-name`, and to find a connection instance with a given name use `find-database`. To print status information about the existing connections, call `status`.

To close a connection to a database, use `disconnect`.

To reestablish a connection to a database, use `reconnect`.

19.2.5.1 Connection example

The following example assumes that the `:odbc` database type has been initialized as described in “Initialization functions and variables” on page 227. It connects to two databases, `scott` and `personnel`, and then prints out the connected databases.

```
(setf *default-database-type* :odbc)
(connect "scott")
(connect "personnel" :database-type :odbc)
(print *connected-databases*)
```

19.2.6 Connecting to Oracle

For *database-type* `:oracle`, *connection-spec* conforms to the canonical form described for `connect`. The *connection* part is the string used to establish the connection. When connecting to a local server, it may be the SID, otherwise it is an alias recognized by the names server, or in the `tnsnames.ora` file.

To connect to Oracle via SQL*Net, *connection-spec* is of the form ***username/password@host*** where *host* is an Oracle hostname.

Common SQL uses the Oracle Call Interface internally where this is available. For Oracle version 8, Common SQL automatically uses the same API as in LispWorks 4.4. On some platforms, this can also be obtained by using **database-type :oracle8**. Note that the **:oracle8** database type is restricted because it cannot access or manipulate LOBs and all connections must use the same character set.

19.2.7 Connecting to ODBC

For **database-type :odbc** or **:odbc-driver**, *connection-spec* may take the canonical form described for `connect`, but an additional syntax is also allowed.

`connect` keyword arguments **:encoding**, **:signal-rollback-errors** and **:date-string-format** are all ignored.

19.2.7.1 Connecting to ODBC using a string

connection-spec should have one of the forms:

username/password@dsn The general form.

dsn/username/password For backward compatibility.

The two forms of strings are distinguished by the presence (or absence) of the '@' character. In both forms, *password* can be omitted along with the preceding '/'. Also, *username* can simply be omitted.

Note that this means that "**xyz**" and "@**xyz**" are both interpreted to give the same values (*username* is null, *password* is null, *dsn* is "**xyz**").

19.2.7.2 Connecting to ODBC using a plist

In the plist, the acceptable keywords are **:username**, **:password**, **:dsn** and **:connection**.

:connection is a synonym of **:dsn**.

19.2.8 Connecting to MySQL

For *database-type* :`mysql`, *connection-spec* may be in the canonical form described for `connect`, but it may also have the extensions described in this section.

In both the string and plist forms of *connection-spec* described below, any part that is omitted defaults to the MySQL default:

<i>username</i>	anonymous user
<i>password</i>	No password
<i>dbname</i>	No default database
<i>hostname</i>	localhost
<i>port</i>	3306 (unless using <i>unix-socket</i>).

19.2.8.1 Connecting to MySQL using a string

connection-spec can be a string of the form:

`username/password/dbname@hostname:port`

where *port* is a decimal number specifying the port number to use. *port* can be omitted along with the preceding ':'.

hostname can be omitted. If *port* is omitted too, the '@' can be omitted as well. If *port* is supplied and *hostname* is not supplied, then both the '@' and the ':' are required, for example:

```
me/my-password/my-db@:3307
```

hostname may also specify a unix socket name, which must start with the character '/'.

dbname may be omitted along with the preceding '/'.

password may be omitted. If *dbname* is also omitted, the preceding '/' can be omitted too.

username may be omitted.

19.2.8.2 Connecting to MySQL using a plist

connection-spec can be a plist containing (some of) the keywords `:username`, `:password`, `:dbname`, `:hostname`, `:port`, `:connection`, `:unix-socket`.

Each of these keywords may be omitted.

If `:unix-socket` is specified, then none of `:hostname`, `:port` and `:connection` can be specified. If `:hostname` is specified then `:connection` must not be specified. The value supplied for `:hostname` can be a raw hostname, or a string of the form *hostname*:*port*. If `:connection` is specified then it can a string conforming to one of these patterns:

<i>hostname</i> <i>hostname</i> : <i>port</i> <i>:port</i> <i>unix-socket</i>	Must start with '/'
--	---------------------

That is, the value *connection* supplied in a plist *connection-spec* is interpreted just like the part of a string *connection-spec* following the '@' character.

19.2.8.3 Locating the MySQL client library

The MySQL interface to initialize, it must find the appropriate MySQL client library. The special variables `*mysql-library-path*`, `*mysql-library-directories*` and `*mysql-library-sub-directories*` give you control over this.

19.2.8.4 Special instructions for MySQL on Mac OS X

Download the 32-bit or 64-bit MySQL package to match your LispWorks image.

The downloadable packages from the MySQL web site contain only static client libraries, but LispWorks needs a dynamic library. You need to create the dynamic library, for example by using the following shell command.

To build the 32-bit dynamic library:

```
gcc -dynamiclib -fno-common \
-o /usr/local/mysql/lib/libmysqlclient_r.dylib \
-all_load /usr/local/mysql/lib/libmysqlclient_r.a -lz
```

To build the 64-bit dynamic library:

```
gcc -m64 -dynamiclib -fno-common \
-o /usr/local/mysql/lib/libmysqlclient_r.dylib \
-all_load /usr/local/mysql/lib/libmysqlclient_r.a -lz
```

This command should be executed as the root user, or some other user with write permission to the `/usr/local/mysql/lib` directory and assumes that MySQL was installed in `/usr/local/mysql`, which is the location used by the prepackaged downloads.

An alternate way to create a dynamic library is to build MySQL from its source code with the `--enable-shared` flag.

By default, LispWorks expects to find the library either in `/usr/local/mysql/lib` or on the shared library path. This can be overridden by setting the special variable `*mysql-library-directories*`.

By default, LispWorks expects the library to be called `libmysqlclient.*.dylib` and it searches for a library that matches that pattern, where * is any version number. This search can be avoided by setting `*mysql-library-path*` to something other than the default `("-lmysqlclient")`, for example, it is possible to force LispWorks to look for version 12 by evaluating

```
(setq *mysql-library-path* "libmysqlclient.12")
```

You can also set `*mysql-library-path*` to a full path, which avoids the need to set `*mysql-library-directories*`.

If the environment variable `LW_SQL_LIBRARY` is set, then its value is used instead of the value of `*mysql-library-path*`.

19.2.9 Connecting to PostgreSQL

For `database-type :postgresql`, `connection-spec` must be either a string in the format specified by the PostgreSQL libraries or a plist.

19.2.9.1 Connecting to PostgreSQL using a string

If `connection-spec` is a string then it should be in the format specified by

www.postgresql.org/docs/7.4/static/libpq.html#LIBPQ-CONNECT

For example,

```
dbname=test user=scott password=tiger host=scandium
```

19.2.9.2 Connecting to PostgreSQL using a plist

connection-spec can be a plist containing (some of) the keywords `:username` (or `:user`), `:password`, `:dbname`, `:hostname` (or `:host`), `:port`, `:connection`. Each of these keywords may be omitted, but if `:connection` is specified, then `:hostname` and `:port` must not be specified.

The value supplied for `:hostname` can be a raw hostname or a string of the form `hostname:port`. The value supplied for `:port` can be an integer or a string naming a service.

If `:connection` is specified then it can be a string conforming to one of these patterns:

hostname

hostname:port

The values should not be escaped or quoted: LispWorks will escape and quote it as needed before passing it to the PostgreSQL library.

19.2.10 Escaping and standard_conforming_strings

LispWorks sets the PostgreSQL session variable

`standard_conforming_strings` to `on` to match the escaping that Common SQL uses. Note that this variable is only available in PostgreSQL 8.2 and later, so escaping will not work correctly in older versions of PostgreSQL.

19.3 Functional interface

The functional interface provides a full set of Data Manipulation and Data Definition functions. The interface provides a SQL-compatible means of querying and updating the database from Lisp. In particular, the values returned from the database are Lisp values — thus smoothly integrating user applications with database transactions. An embedded syntax is provided for dynamically constructing sophisticated queries through `select`. Iteration is also provided via a mapping function and an extension to the `loop` macro. If

19.3 Functional interface

necessary, the basic functions `query` and `execute-command` can be called with SQL statements expressed as strings. It is also possible to update or query the data dictionary.

19.3.1 Functional Data Manipulation Language (FDML)

The functions available for Data Manipulation and Data Definition are described below.

19.3.1.1 Querying

The function `select` returns data from a database matching the constraints specified. The data is returned, by default, as a list of records in which each record is represented as a list of attribute values.

Database identifiers used in `select` are conveniently specified using the symbolic SQL `[]` syntax. This syntax is enabled by calling `enable-sql-reader-syntax`.

The square bracket syntax assumes that sql symbols are visible. Therefore when using the `[]` syntax, ensure that the current package either is `sql`, or is a pacakge which has the `sql` package on its package-use-list.

For a description of the symbolic SQL syntax see Section 19.5 on page 247. For example, the following is a potential query and its result:

```
(select [person_id] [person surname] :from [person])
=>
((111 "Brown") (222 "Jones") (333 "Smith"))
("PERSON_ID" "SURNAME")
```

In this example, `[person_id]`, `[person surname]` and `[person]` are database-identifiers and evaluate to literal SQL. The result is a list of lists of attribute values. Conversely, consider

```
(select [surname] :from [person] :flatp t)
=>
("Brown" "Jones" "Smith")
("SURNAME")
```

In this case the result is a simple list of surname values because of the use of the `flatp` keyword. The `flatp` keyword only works when there is one column of data to return.

In this example we use `*` to match all fields in the table, and then we use the `result-types` keyword to specify the types to return:

```
(select [*] :from [person])
=>
((2 111 "Brown") (3 222 "Jones") (4 333 "Smith"))
("ID" "Person_ID" "Surname")

(select [*] :from [person] :result-types '(:integer :string
:string)
=>
((2 "111" "Brown") (3 "222" "Jones") (4 "333" "Smith"))
("ID" "Person_ID" "Surname")
```

If you want to affect the result type for a specified field, use a type-modified database identifier. As an example:

```
(sql:select [Person_ID :string] [Surname] :from [person])
=>
(("111" "Brown") ("222" "Jones") ("333" "Smith"))
("PERSON_ID" "SURNAME")
```

With `database-type :mysql`, further control over the values returned from queries is possible as described in “Types of values returned from queries” on page 261.

In this final example the `:where` keyword is used to specify a condition for returning selected values from the database.

```
(select [surname] :from [person] :where [= [person_id] 222])
=>
(("Jones"))
("SURNAME")
```

To output the results of a query in a more easily readable tabulated way, use the function `print-query`. For example the following call prints two even columns of names and salaries:

```
(print-query [select [surname] [income] :from [employee]
:titled '("NAME" "SALARY")')

NAME      SALARY
Brown    22000
Jones    45000
Smith    35000
```

19.3.1.2 Modification

Modifications to the database can be done using the following functions; `insert-records`, `delete-records` and `update-records`. The functions `commit`, `rollback` and the macro `with-transaction` are used to control transactions. Although `commit` or `rollback` may be used in isolation it is advisable to do any updates inside a `with-transaction` form instead. This provides consistency across different database transaction models. For example, some database systems do not provide an explicit “start-transaction” command while others do. `with-transaction` allows user code to ignore database-specific transaction models.

The function `insert-records` creates records in a specified table. The values can be either specified directly with the argument `values` or in the argument `av-pairs`, or they can be the result of a query specified in the `query` argument. The attributes can be specified with the argument `attributes` or in the argument `av-pairs`.

If `attributes` is supplied then `values` must be a corresponding list of values for each of the listed attribute names. For example, both:

```
(insert-records :into [person]
  :attributes '(person_id income surname occupation)
  :values '(115 11000 "Johnson" "plumber"))
```

and:

```
(insert-records :into [person]
  :av-pairs `((person_id 115)
    (income 11000)
    (surname "Johnson")
    (occupation "plumber")))
```

are equivalent to the following SQL:

```
INSERT INTO PERSON
  (PERSON_ID, INCOME, SURNAME, OCCUPATION)
VALUES (115, 11000, 'Johnson', 'plumber')
```

If `query` is provided, then neither `values` nor `av-pairs` should be. In this case the attribute names in the query expression must also exist in the insertion table. For example:

```
(insert-records :into [person]
  :query [select [id] [firstname] [surname]
          :from [manager]]
  :attributes '(person_id firstname surname))
```

To delete or alter those records in a table which match some condition, use `delete-records` or `update-records`.

19.3.1.3 Caching of table queries

Operations which add or modify records sometimes need to perform an internal query to obtain type information for the relevant attributes. In principle it is possible for the database schema to change between update operations, and hence this query is run for each update operation. This can be a significant overhead.

For tables which are guaranteed to have a constant schema, you can optimize performance by adding a cache of these internal query results, using the function `cache-table-queries`. This can also be used to reset the cache if the table schema is actually altered. To control the default caching behavior throughout every database connection, you can set the variable `*cache-table-queries-default*`.

19.3.1.4 Transaction handling

A transaction in SQL is defined as *starting from* the `connect`, or from a `commit`, `rollback` or data-dictionary update and *lasting until* a `commit`, `rollback`, data-dictionary update or a `disconnect` command.

The macro `with-transaction` executes a body of code and then does a commit, unless the body failed in which case it does a rollback. Using this macro allows your code to cope with the fact that transactions may be handled differently in the different vendor implementations. Any differences are transparent if the update is done within a `with-transaction` form.

Note: Common SQL opens an ODBC database in manual commit mode, so that `with-transaction` and `rollback` take effect.

Applications should perform all database update operations in a `with-transaction` form (or follow them with `commit` or `rollback`) in order to

19.3 Functional interface

safely commit or discard their changes. This applies to operations that modify either the data or the schema.

The following example shows a series of updates to an employee table within a transaction. This example would commit the changes to the database on exit from `with-transaction`. This example inserts a new record into the `emp` table, then changes those employees whose department number is 40 to 50 and finally removes those employees whose salary is more than 300,000.

```
(connect "personnel")

(with-transaction
  (insert-records :into [emp]
    :attributes '(empno ename job deptno)
    :values '(7100 "ANDERSON" "SALESMAN" 30))
  (update-records [emp]
    :attributes [deptno]
    :values 50
    :where [= [deptno] 40])
  (delete-records :from [emp]
    :where [> [sal] 300000]))
```

To commit or roll back all changes made since the last commit, use the functions `commit` or `rollback`.

19.3.1.5 Iteration

Common SQL has three iteration constructs: a `do` loop, a mapping function, and an extension to the Common Lisp `loop` macro.

The macros `do-query` and `simple-do-query` repeatedly execute a piece of code within the scope of variables bound to the attributes of each record resulting from a query.

The function `map-query` maps a function across the results of a query and returns its result in a sequence of a specified type, like the Common Lisp `map` function.

Common SQL provides an extension to the ANSI Common Lisp macro `loop` which is a clause for iterating over query results. The syntax of the clause is:

```
{for|as} var [type-spec] being
  {the|each}{tuples|tuple}
  {in|of} query-expression
```

query-expression can be a string, a SQL expression (a result of the [..] syntax) or a prepared statement (a result of `prepare-statement`).

The more general word `tuple` is used so that it can also be applied to the object-oriented case. In the functional case, `tuple` is synonymous with `record`.

Each iteration of the loop assigns the next record of the table to the variable `var`. The record is represented in Lisp as a list. Destructuring can be used in `var` to bind variables to specific attributes of the records resulting from *query-expression*. In conjunction with the panoply of existing clauses available from the `loop` macro, the new iteration clause provides an integrated report generation facility.

Suppose the name of everyone in an employee table is required. This simple query is shown below using the different iteration method. The function `map-query` requires `flatp` to be specified; otherwise each name would be wrapped in a list.

```
(do-query ((name) [select [ename] :from [emp]])
          (print name))

(map-query
  nil
  #'(lambda (name) (print name))
  [select [ename] :from [emp] :flatp t])

(loop for (name)
      being each tuple in
      [select [ename] :from [emp]]
      do
  (print name))
```

The following extended `loop` example binds, on each record returned as a result of the query, `name` and `salary`, accumulates the salary, and for salaries greater than 2750 increments a count, and prints the details. Finally, the average salary is printed.

19.3 Functional interface

```
(loop for (name salary) being each record in
      [select [ename] [sal] :from [emp]]
      initially (format t "~~~20A~10D" 'name 'salary)
      when (and salary (> salary 2750))
          count salary into salaries
          and sum salary into total
          and do (format t "~~~20A~10D" name salary)
      else
          do (format t "~~~20A~10D" name "N/A")
      finally
        (format t "2&Av Salary: ~10D" (/ total salaries)))
```

19.3.1.6 Specifying SQL directly

Sometimes it is necessary to execute vendor-specific SQL statements and queries. For these occasions Common SQL provides the functions `query` and `execute-command`. They can also be used when the exact SQL is known in advance and thus the square bracket syntax is not needed. The query expression can be a string, a SQL expression (a result of the [...] syntax) or a prepared statement (a result of `prepare-statement`).

The function `query` runs a SQL query on a database and returns a list of values like `select` (see “Querying” on page 235). It also returns a list of the field names selected.

`execute-command` is the basic function which executes any SQL statement other than a query. It can run a stored procedure, as described in `execute-command`, page 995.

19.3.1.7 Building vendor-specific SQL

Common SQL does not provide a general interface to vendor-specific syntax.

There are two approaches you can take with SQL such as this:

```
SELECT B.PARTY_CODE_ALIAS, A.VALUE FROM CODES A, CODE_ALIASES B
  WHERE A.DOMAIN=B.CODE_DOMAIN(+) AND A.VALUE=B.CODE_VALUE(+)
    AND B.PARTY_ID(+)=<party_id>
```

1. Construct the string as above and then call `query` as described in “Specifying SQL directly” on page 241.
2. Use `sql-expression` to construct the vendor-specific pieces of the SQL. The above expression can be written like this:

```
(sql:select [b party_code_alias] [a value]
  :from '([codes a] [codes_aliases b])
  :where [and [= [a domain]
    (sql:sql-expression
      :string "B.CODE_DOMAIN(+)")
    [= (sql:sql-expression
      :string "B.PARTY_ID(+)" PARTY-ID)])
  ])
```

19.3.2 Functional Data Definition Language (FDDL)

Functions in the FDDL may be used to change or query the structure of the database.

19.3.2.1 Querying the schema

The functions `list-tables`, `list-attributes`, `attribute-type` and `list-attribute-types` return information about the structure of a database.

19.3.2.2 FDDL Querying example

This example shows you how to query the type of the `ename` attribute of the `emp` table.

```
(attribute-type [ename] [emp]) -> :char
```

19.3.2.3 Modification

You may create or drop (delete) tables using the functions `create-table` and `drop-table`.

Create or drop indexes using the functions `create-index` and `drop-index`.

To create or drop a view (that is, a derived table based on a query) use the functions `create-view` and `drop-view`.

19.4 Object oriented interface

This section describes the object-oriented interface to SQL databases using specialized CLOS classes. These classes have `standard-db-object` as one of their superclasses and have a common metaclass which provides the special-

19.4 Object oriented interface

ized behavior for mapping subclasses of `standard-db-object` onto records in the database. A class of this kind is created using `def-view-class`.

19.4.1 Object oriented/relational model

In the simple case, a class maps onto a database table, an instance of the class maps onto a record in the table, and a slot in the class maps onto an attribute in the table.

In general, however, a class maps onto a database view, an instance of the class maps onto a collection of records in the view, and a slot in the class is either:

- A *base slot* that maps onto an attribute in the view
- A *join slot* that points to a list of other view-class instances

If an instance maps onto more than one record in the view then for each record, all the key attributes from each table in the view are the same.

19.4.1.1 Inheritance for View Classes

It is not possible to inherit from a class that was defined by `def-view-class`. All of the slots need to be in the same class (and hence also in the same SQL table).

19.4.2 Object-Oriented Data Definition Language (OODDL)

The OODDL lets you define a mapping between the relational and object-oriented worlds to be defined. Through the mapping a CLOS object can effectively denote a collection of records in a database view, and can contain pointers to other view-based CLOS objects. The CLOS object makes explicit an object implicitly described by the flat relational values.

The mapping is defined using the macro `def-view-class`. This extends the syntax of `defclass` to allow special *base slots* to be mapped onto the attributes of database views (presently single tables). When you submit a `select` query that names a View Class (that is, a class defined by `def-view-class`), then the corresponding database view is queried, and the slots in the resulting instances are filled with attribute values from the database.

It is also possible to create *join slots* and *virtual* (ordinary) *slots*.

All the special slots are distinguished by a modified set of class and slot options. The special slots and their options are described in more detail under `def-view-class` in the *LispWorks Reference Manual*.

Note: `def-view-class` defines a Lisp view of an underlying database table. It is a similar concept to that of SQL VIEWS, but does not interact with them.

You can create a table based on a View Class using the function `create-view-from-class` and delete it using the function `drop-view-from-class`.

19.4.2.1 Example View Class definition

The following example shows a View Class corresponding to the traditional employees table, with the employee's department given by a join with the departments table. See `def-view-class`, page 979 for a description of the slot options.

19.4 Object oriented interface

```
(def-view-class employee (standard-db-object)
  ((employee-number :db-kind :key
                    :column empno
                    :type integer)
   (employee-name :db-kind :base
                  :column ename
                  :type (string 20)
                  :accessor employee-name)
   (employee-department :db-kind :base
                         :column deptno
                         :type integer
                         :accessor employee-department)
   (employee-job :db-kind :base
                 :column job
                 :type (string 9))
   (employee-manager :db-kind :base
                     :column mgr
                     :type integer)
   (employee-location :db-kind :join
                       :db-info (:join-class department
                                         :retrieval :deferred
                                         :set nil
                                         :home-key employee-department
                                         :foreign-key department-number
                                         :target-slot department-loc)
                       :accessor employee-location))
   (:base-table emp))
```

The `def-view-class` macro allows elements or lists of elements to follow `:home-key` and `:foreign-key`. The elements can be symbols, `nil`, strings, integers or floats.

This syntax means that an object from the join class is only included in the join slot if the values from `home-key` are equal to the values in `foreign-key`, in order. These values are calculated as follows:

- If the element in the list is a symbol it is taken to be a slot name and the value of the slot is used
- Otherwise the element is taken to be the value

Note that some database vendors may have short maximum identifier lengths. The CLOS interface uses constructed alias names for tables in its SQL queries, and long table names or long class names may cause the constructed aliases to exceed the maximum identifier length for a particular vendor.

19.4.3 Object-Oriented Data Manipulation Language (OODML)

The OODML is designed to be powerful and expressive, while remaining familiar to users of the FDML. To achieve this aim, some of the functions and macros in the SQL interface have been *overloaded* — particularly the `select` function and the iteration constructs.

The function `select` is common across the both the functional and object-oriented SQL interfaces. If its first argument, `selections`, refers to a View Class by supplying its symbolic name then the select operation becomes object-oriented and it returns a list of instances instead of a list of attributes.

A subsequent equivalent `select` call will return the same (`eq1`) instances. The `:refresh` argument can be used to ensure that existing instances get updated with any changed data. If such an update requires action by your application, then add methods on the generic function `instance-refreshed`.

In a View Class `select` call, the symbol `slot-value` is a valid SQL operator for use within the `:where` argument.

To find the View Classes for a particular database, use the function `list-classes`.

To manipulate data via a View Class, that is to modify the records corresponding to instances of the View Class, using the generic functions `update-records-from-instance`, and `update-record-from-slot`.

To delete records corresponding to instances of the View Class, use the generic function `delete-instance-records`.

To update existing instances of a View Class when data is known to have changed, use the generic functions `update-slot-from-record` and `update-instance-from-records`.

19.4.3.1 Examples

```
[select 'employee']
-> #<SQL-OBJECT-QUERY (EMPLOYEE)>
```

19.5 Symbolic SQL syntax

```
(select 'employee
       :where [= [slot-value 'employee 'employee-job]
              "SALESMAN"])
((#<db-instance EMPLOYEE 8067092>)
 (#<db-instance EMPLOYEE 8069536>)
 (#<db-instance EMPLOYEE 8069176>)

(list-classes)
(#<db-class EMPLOYEE> #<db-class DEPARTMENT>)
```

19.4.3.2 Iteration

The object-oriented SQL interface has the same three iteration constructs as the functional interface (see Section 19.3.1.5 on page 239): a `do-loop`, a mapping function, and an extension to the Common Lisp `loop` macro. However, in this case, the iteration focus is not a tuple of attributes (that is, a record), but a tuple of instances. For example:

```
(loop for (jones company) being the tuples in
      [select 'person 'organisation
      :where [= [slot-value 'person 'surname] "Jones"]]
      do (format t "~A ~A ~%" 
                 (slot-value jones 'forename)
                 (slot-value company 'short-name)))
```

Note: Instances may denote many database records, and hence the effective iteration focus in this case is a tuple of sets of tuples of attributes.

19.4.3.3 Garbage collection of view instances

View instance objects are not released for garbage collection (GC) until the connection is closed. This is because they are referenced by the CLOS object representing the database connection. This is to ensure that they can reliably be compared by `eq`.

19.5 Symbolic SQL syntax

Common SQL supports a symbolic query syntax across both the functional and object-oriented interface layers. It allows SQL and Common Lisp expressions to be mixed together — with as much processing as possible done at compile-time. Symbolic SQL expressions are read as square-bracketed lists to

distinguish them from Lisp expressions. However, each can be nested within the other to achieve the desired result.

By default, this reader syntax is turned off. To turn it on see Section 19.5.3 on page 254.

19.5.1 The “[...]" Syntax

The square bracket syntax for the SQL interface is heavily overloaded to provide the most intuitive behavior in all situations. There are three uses of square brackets:

1. To enclose a database identifier
2. To construct a SQL string representing a symbolic expression
3. To enclose literal SQL

Each of these uses is demonstrated below.

19.5.1.1 Enclosing database identifiers

Database identifiers can be enclosed in the square bracket syntax as shown in the following examples.

```
[foo] => #<SQL-IDENT "FOO">
```

This case corresponds to an unqualified SQL identifier as in: `SELECT FOO FROM BAR.`

```
[foo bar] => #<SQL-IDENT "FOO.BAR">
```

This corresponds to a qualified SQL identifier as in:
`SELECT FOO.BAR FROM FOO`

```
["foo" bar] => #<SQL-IDENT "\"foo\".BAR">
```

This corresponds to a qualified SQL identifier with an aliased table name containing special characters as in:
`SELECT "foo".BAR FROM BAZ "foo".`

19.5 Symbolic SQL syntax

```
[foo "bar"] => #<SQL-IDENT FOO \"bar\">
```

This corresponds to an alias definition as in:

```
SELECT "bar".* FROM FOO "bar".
```

```
[foo :integer] => #<SQL-IDENT "FOO" :INTEGER>
```

As above, but including a type coercion component.

```
[foo bar :integer] -> #<SQL-IDENT "FOO.BAR" :INTEGER>
```

As above, but includes a type coercion component.

```
["foo" bar :integer] -> #<SQL-IDENT "\\"foo\\".BAR" :INTEGER>
```

As above, but includes a type coercion component.

19.5.1.2 SQL strings representing symbolic expressions

There are some SQL operators which may take a single argument (for example `any`, `some`, `all`, `not`, `union`, `intersect`, `except`, and `minus`). These are read as calls to the appropriate SQL operator. For example:

```
[any '(3 4)] -> #<SQL-VALUE-EXP "(ANY (3,4))">
```

This causes no conflict, however, as it is illegal to use these reserved words as identifiers in SQL. Similarly with two argument operators:

```
[> [baz] [beep]]  
-> #<SQL-RELATIONAL-EXP "(BAZ > BEEP)">
```

The `select` statement itself may be prepared for later query execution using the `[]` syntax. For example:

```
[select [person_id] [surname] :from [person]]
```

This form results in a SQL expression, which could be bound to a Lisp variable and later given to `query` to execute. For example:

```
[select [foo] [bar *]
       :from '([baz] [bar])
       :where [or [= [foo] 3]
              [> [baz.quux] 10]]]
->
#<SQL-QUERY
  "(SELECT FOO,BAR.* FROM BAZ,BAR
   WHERE ((FOO = 3)
          OR (BAZ.QUUX > 10)))">
```

Strings can be inserted in place of database identifiers within a `select`:

```
[select [foo bar] [baz]
       :from '([foo] [quux])
       :where [or [> [baz] 3]
              [like [foo bar] "SU%"]]]
->
#<SQL-QUERY:
  "(SELECT FOO.BAR,BAZ
   FROM FOO,QUUX
   WHERE ((BAZ > 3)
          OR (FOO.BAR LIKE 'SU')))">
```

Any non-constant included gets filled in at runtime, for example:

```
[> [foo] x]
```

when macroexpanded reads as

```
(SQL-> #<SQL-IDENT "FOO"> x)
```

which constructs the actual SQL string at runtime.

Any arguments to a SQL operator that are Lisp constants are translated to the matching SQL construct at compile-time, for example:

```
"foo" -> "'foo'"
3 -> "3"
'("this" 5 "that") -> "('this', 5, 'that')"
'xyz -> "XYZ"
```

SQL operators which are supported are `null`, `exists`, `*`, `+`, `/`, `-`, `like`, `substr`, `and`, `or`, `not`, `in`, `all`, `any`, `some`, `|`, `=`, `<`, `>`, `>=`, `<=`, `<>`, `order-by`, `count`, `max`, `min`, `avg`, `sum`, `minus`, `nvl`, `distinct`, `except`, `intersect`, `union`, `slot-value`, `between` and `userenv`. There are also pseudo operators for calling database functions (see “Calling database functions” on page 252).

19.5 Symbolic SQL syntax

The general syntax is: [<operator> <operand> ...], for instance:

```
(select [count [*]] :from [emp])
```

The operand can itself be a SQL expression, as in the following example:

```
(sql:create-table [company]
                  '(([name] (varchar 20) not-null)))

(loop for company in '("LispWorks Ltd"
                        "Harlequin"
                        "Oracle"
                        "Rover"
                        "Microsoft")
      do
      (sql:insert-records :into [company]
                           :av-pairs `(([name] ,company)))))

(sql:create-table [person]
                  '(([surname] (varchar 20) not-null)
                     ([firstname] (varchar 20) not-null)))

(loop for person in '(("Joe" "Bloggs")
                        ("Fred" "Smith")
                        ("Rover" "the Dog")
                        ("Fido" "the Dog"))
      do (sql:insert-records :into [person]
                            :av-pairs
                            `(([firstname] ,(car person))
                               ([surname] ,(second person)))))

(sql:select [name]
            :from [company]
            :where [= [name]
                    [any [select [surname]
                          :from [person]]]])

(sql:select [surname]
            :from [person]
            :set-operation [union [select [firstname]
                                  :from [person]]])
```

19.5.1.3 Calling database functions

An arbitrary function can be included in the SQL using the pseudo operator `sql-function`. The first argument is the function name and the rest are its arguments, for example:

```
(select [sql-function "COS" [age]] :from [EMPLOYEES])

(insert-records
  :into [atable]
  :attributes '(a b)
  :values
  (list 1 [sql-function "TO_DATE" "02/06/99" "mm/DD/RR"]))
```

Also you can call SQL infix operators using the pseudo operators `sql-boolean-operator` and `sql-operator`.

19.5.1.4 Enclosing literal SQL

Literal SQL statements can simply be enclosed in the square bracket syntax, as shown below.

Creating a full query (which can be used as argument to `query`):

```
["SELECT FOO, BAR FROM BAZ"]
-> #<SQL "SELECT FOO, BAR FROM BAZ">
```

Using an unportable function condition in `:where`:

```
(sql:select [*] :from ["aTable"]
  :where ["unportable_function() > 89"])
```

19.5.2 Programmatic interface

In some cases it is necessary to build SQL-expressions dynamically under program control.

The function `sql-operation` returns the SQL expression for an operator applied to its arguments. It also supports building SQL expressions which contain arbitrary SQL functions using the pseudo operators `sql-function`, `sql-operator` and `sql-boolean-operator`. For examples see `sql-operation`, page 1074.

19.5 Symbolic SQL syntax

The function `sql-expression` makes a SQL expression from the given keywords. This is equivalent to the first and third uses of the `[]` syntax as discussed in Section 19.5.1 on page 248.

The function `sql-operator` returns the Lisp symbol for a SQL operator.

The function `sql` makes SQL out of the arguments supplied. Each argument to `sql` is turned into SQL and then the `args` are concatenated with a single space between each pair. A Lisp string maps to the same characters enclosed between single quotes (this corresponds to a SQL string constant). `nil` maps to `"NULL"`, that is, a SQL null value. Symbols and numbers map to strings. A list maps to a parenthesised, comma-separated expression. A vector maps to a comma-separated expression, which allows the easy generation of SQL lists that require no parentheses such as table lists in select statements.

The rules for the conversion are fully specified in `sql`, page 1068.

19.5.2.1 Examples

The following example function, taken from the object-oriented SQL interface layer, makes a SQL query fragment that finds the records corresponding a CLOS object (using the slots as attributes), when built into the `where-clause` of an updating form.

```
(let* ((class (class-of object))
       (key-slots (db-class-keyfields class)))
  (loop
    for key in key-slots
    for slot-name = (slot-definition-name key)
    for slot-type = (db-slot-definition-type key)
    collect
      [= (make-field-name class key)
        (lisp-to-sql-format
          (slot-value object slot-name)
          (if (listp slot-type)
              (car slot-type)
              slot-type))]
    into cols
    finally (apply (sql-operator 'and) cols)))
->
#<SQL-RELATIONAL-EXP "(EMP.EMPNO = 7369)">
```

Here is another example that produces a SQL `select` statement:

```

(sql-operation 'select
  (sql-expression :table 'foo
    :attribute 'bar)
  (sql-expression :attribute 'baz)
:from (list
  (sql-expression :table 'foo)
  (sql-expression :table 'quux)))
:where (sql-operation 'or
  (sql-operation '>
    (sql-expression :attribute 'baz)
  3)
  (sql-operation 'like
    (sql-expression :table 'foo
      :attribute 'bar)
    "SU%")))
->
#<SQL-QUERY "SELECT FOO.BAR,BAZ FROM FOO,QUUX
 WHERE ((BAZ > 3) OR (FOO.BAR LIKE 'SU%'))">
```

19.5.3 Utilities

The function `enable-sql-reader-syntax` switches square bracket syntax on and sets the state so that `restore-sql-reader-syntax-state` restores the syntax again if it is subsequently disabled. The function `disable-sql-reader-syntax` switches square bracket syntax off and sets the state so that `restore-sql-reader-syntax-state` disables the syntax again if it is subsequently enabled.

The functions `locally-enable-sql-reader-syntax` and `locally-disable-sql-reader-syntax` switch square bracket syntax on and off, but do not change the state restored by `restore-sql-reader-syntax-state`. The intended use of these is in a file:

```

#. (locally-enable-sql-reader-syntax)
  <code using [...]>
#. (restore-sql-reader-syntax-state)
```

19.6 Working with date fields

This section describes particular issues around using datetime database fields via Common SQL.

19.6 Working with date fields

See also “Types of values returned from queries” on page 261 for information specifically about returning datetime values from MySQL.

19.6.1 Testing date values

Compare DATE values by formatting the date as a string in a date format that the database can parse. For example:

```
(sql:select * :from [Table] :where [= [Date] "25-Dec-2005"])
```

Note that it is not possible to lookup date values in the database using numeric values. This is because:

1. Common SQL cannot know that the field will be a date field until the results are returned, and
2. the database probably does not know about Common Lisp universal time.

19.6.2 DATE returned as universal time

By default Common SQL converts DATE values to Common Lisp universal times. Therefore code like this returns Common Lisp universal times (that is, integers) where `MyDate` is a DATE field type:

```
(sql:select [MyDate] :from [MyTable] :where [= [id] 1])
```

19.6.2.1 Timezone of returned DATEs

Common SQL creates universal time values from DATE fields assuming that the database contains times in Coordinated Universal Time (UTC). That is, as if by passing `time-zone 0` to `encode-universal-time`. To decode the values consistently with this encoding, pass `time-zone 0` to `decode-universal-time`.

If the database contains times in a different timezone, then the integer `time-zone` needs to be adjusted by adding an appropriate multiple of 3600 before calling `decode-universal-time`.

19.6.3 DATE returned as string

Instead of universal time integers, you can obtain strings formatted by the database by modifying the `MyDate` database identifier, adding `:string` like this:

```
(sql:select [MyDate :string] :from [MyTable] :where [= [id] 1])
```

This avoids the overhead of converting DATEs to universal times and so may improve performance of your application.

See `select`, page 1062 for details.

19.6.4 Using universal time format

If the database is only accessed via Common SQL and you want to use the universal time date format, then you might consider using an INTEGER column containing universal time values instead of a DATE column.

19.7 SQL I/O recording

It is sometimes convenient to simply monitor the flow of commands to, and results from, a database. A number of functions are provided for this purpose.

The functions operate on two stream collections (*broadcast streams*) — one each for commands and results. They allow the recording to be started and stopped, checked, or recorded on further individual streams. By default, both commands and results recording is printed only to `*standard-output*`.

For details, see the reference pages for `start-sql-recording`, `stop-sql-recording`, `sql-recording-p`, `list-sql-streams`, `sql-stream`, `add-sql-stream` and `delete-sql-stream`.

19.8 Error handling in Common SQL

All errors generated by Common SQL are of type `sql-user-error` or `sql-database-error`. You can test for these conditions and their subtypes in your error handlers.

19.8.1 SQL condition classes

An `sql-user-error` is an error inside Lisp.

An `sql-database-error` is an error inside the database interface that Lisp uses.

The following are subclasses of `sql-database-error`:

`sql-database-data-error`

An error with the data given. It signifies an error that must be fixed for the code to work.

`sql-timeout-error`

Signifies an error that is a result of other users using the same database. It means the code can work without change, once the other users stop using the database.

`sql-connection-error`

An error with the connection to the RDBMS.

The following are subclasses of `sql-connection-error`:

`sql-timeout-error`

A timeout with some operation.

`sql-fatal-error`

An error which means that the connection is no longer usable.

Note: In general, the documentation for the various supported databases make it difficult to decide which error code should be made into which of the above condition class, and we probably get many of these wrong. If you find errors that seem to be signalled with the wrong condition class, please report them to Lisp Support, including the full printout of the condition, and we will fix it.

19.8.2 Database error accessors

Three functions are provided which access slots of `sql-database-error`, allowing you to discover more about the actual error that occurred.

`sql-error-error-id` and `sql-error-secondary-error-id` return primary and secondary error identifiers. If you use these, please read the detailed description in `sql-database-error`, page 1070.

`sql-error-database-message` is a string (maybe `nil`) returned by the foreign code.

19.9 Using MySQL

This section describes particular issues in Common SQL with MySQL databases.

19.9.1 Connection specification

See “Connecting to MySQL” on page 231 for information about MySQL specific extensions for the `connection-spec` passed to `connect`.

19.9.2 Case of table names and database names

MySQL is case sensitive on table names and database names when the server is on a Unix machine. MySQL does not automatically change raw names to uppercase as specified by the SQL standard. However, Common SQL is geared towards uppercasing all names, so this may cause some mismatches. In general, Common SQL uppercases strings, and uses symbol names, which are normally uppercase, as-is.

One solution, possible only if you control the naming of tables and databases, is to make them all have the same case. If this is uppercase, that suffices. If it is lowercase, you need to set the variable `lower_case_table_names` in the configuration of the server.

If you cannot make all the names the same case, you have to get the case right. This can be achieved in several ways:

1. Specify tables names using strings, for example:

```
(sql:select [*] :from ["TableNamewithVARIABLEcase"])
```

Note that this does not work in LispWorks 4.4 and previous versions.

2. Pass the Lisp string directly:

```
(sql:select [*] :from "TableNamewithVARIABLEcase")
```

19.9 Using MySQL

Note that in this case the table name is passed to the database inside double quotes. That works only when the mode of the Common SQL connection contains `ANSI_QUOTES` (which is the default, see “SQL mode” on page 259 for details).

3. Specify table names as escaped symbols:

```
(sql:select [*] :from [|TableNamewithVARIABLEcase|])
```

4. Construct the whole query string and pass it to `query` rather than using `select`:

```
(sql:query "select * from TableNamewithVARIABLEcase")
```

19.9.3 Encoding (character sets in MySQL).

You can specify the encoding to be used by passing the `:encoding` argument to `connect`. Common SQL supports various encodings for MySQL as documented in `connect`, page 964.

The default is to use the default for the particular MySQL installation.

19.9.4 SQL mode

Because Common SQL is geared towards ANSI SQL, by default it connects in ANSI mode. If another mode is required, it can be set at connection time.

For example, to make MySQL treat quotes as in ANSI without setting other ANSI features, do:

```
(sql:connect "me/mypassword/mydb"  
             :sql-mode "ANSI_QUOTES")
```

See the description of the `:sql-mode` argument to `connect`, page 964 for details.

19.9.5 Meaning of the `:owner` argument to `select`

In the Common SQL MySQL interface, the value of the `select` keyword argument `:owner` is interpreted to select a database name.

19.9.6 Special considerations for iteration functions and macros

This section describes particular issues when fetching multiple records using Common SQL with MySQL databases.

19.9.6.1 Fetching multiple records

The function `map-query` and the macros `do-query`, `simple-do-query` and `loop` with `each record` use internally `mysql-use-query`, which means that the underlying MySQL code brings the data from the server one record at a time. With a small number of records, it may be preferable to bring all the data immediately instead. This can be done by passing the argument `get-all`, as follows:

```
(sql:map-query nil 'print
  "select forname,surname from people"
  :get-all t)

(sql:do-query
  ((forname surname) "select forname,surname from people"
   :get-all t)
  body)

(sql:simple-do-query
  (list "select forname,surname from people"
    :get-all t)
  body)

(loop for (forname surname) being each record
  "select forname,surname from people"
  get-all t
  body)
```

19.9.6.2 Aborting queries which fetch many records

In the MySQL interface there is no way to abort a query when part way through it. When any of the iterations above stops before reaching its end, the underlying code retrieves all the records to the end of the query (though without converting them to Lisp objects). If the query found many records, that may be an expensive (that is, time consuming) operation.

It is possible to avoid this inefficiency by passing the argument `not-inside-transaction`. If `not-inside-transaction` is true then when a query is aborted, then

19.9 Using MySQL

LispWorks closes the database connection and reopens it, rather than retrieving all the remaining records.

```
(sql:map-query nil 'print
  "select forname, surname from people"
  :get-all t
  :not-inside-transaction t)
```

Note that this will lose any state associated with the connection, and so *not-inside-transaction* should only be used with care.

19.9.7 Table types

By default, `create-table` creates tables of the default type. This behavior can be overridden by the `connect` keyword arguments `:default-table-type` and `:default-table-extra-options`, and the `:type` and `:extra-options` keyword arguments to `create-table`.

If `type` is passed to `create-table` or `default-table-type` was passed to `connect`, it is used as the argument to the "keyword" `TYPE` in the SQL statement:

```
create table MyTable (column-specs) TYPE = type-value
```

If `extra-options` is passed to `create-table` or `default-table-extra-options` was passed to `connect`, it is appended in the end of the SQL statement above.

`connect` with `default-table-type` and `create-table` with `type` also accept the keyword argument `:support-transactions`. When `support-transactions` is true, these functions will attempt to make tables that support transactions. It does this by using the type `innodb`.

19.9.8 Rollback errors

The default value of the `connect` keyword argument `:signal-rollback-errors` is determined by the value of the `:default-table-type` argument. If `default-table-type` is `:support-transactions` or "`innodb`" or "`bdb`", then the default value for `:signal-rollback-errors` is `t`, otherwise the default value is `nil`.

19.9.9 Types of values returned from queries

Common SQL uses the MySQL mechanism that returns values as strings.

By default, Common SQL converts these strings to the appropriate Lisp type corresponding to the column type (or more accurately, the type of the field in the query) according to Table 19.2

Table 19.2 MySQL type mapping

MySQL column type	Lisp Type	Meaning
All integer types	<code>integer</code>	
Double	<code>double-float</code>	
Single	<code>single-float</code>	
Decimal	<code>rational</code>	
All String types	<code>string</code>	
All Binary types	<code>(array (unsigned-byte 8) *)</code>	
Date	<code>integer</code>	Universal time
Datetime	<code>integer</code>	Universal time
Timestamp	<code>integer</code>	Universal time
Time	<code>integer</code>	Number of seconds
Year	<code>integer</code>	Number of years

However, if you specify the result type as `:string`, this eliminates the conversion and the return value is simply the string retrieved by MySQL. For information about specifying the result type for a column (or multiple columns) in a query, see “Querying” on page 235.

Each of the five date-like types (that is, Date, Datetime, Timestamp, Time and Year) can have result type `:date`, `:date-string` or `:datetime-string` with the following effects:

- | | |
|--------------------|---|
| <code>:date</code> | This result type means a Universal time. This is the default except for Year. |
|--------------------|---|

19.10 Using Oracle

:date-string

A string with the format that MySQL uses for Date columns.

:datetime-string

A string with the format that MySQL uses for Datetime columns.

All the numeric types can have result type **:int**, **:single-float** or **:double-float**, causing the appropriate conversion. No check is made on whether the result is actually useful.

String types can have result type **:binary**, which returns an array.

19.9.10 Autocommit

Common SQL sets **autocommit** to 0 when it opens a MySQL connection.

19.10 Using Oracle

This section describes particular issues in Common SQL with Oracle databases, apart from the LOB interface, which is described in “Oracle LOB interface” on page 264.

19.10.1 Connection specification

See “Connecting to Oracle” on page 229 for information about Oracle-specific interpretation of the *connection-spec* passed to **connect**.

19.10.2 Setting connection parameters

Oracle database connections have prefetch values which you can control via Common SQL. Alternatively you can allow the database default prefetch values to take effect.

You can set the default prefetch values for a connection by passing **:prefetch-rows-number** and **:prefetch-memory** keyword arguments to **connect**. The default value of *prefetch-rows-number* is 100 and the default value of *prefetch-memory* is #x100000 (meaning 1MB of data).

You can also pass the value `:default` for either of these arguments. This means that Common SQL does not set the default. This is useful if Oracle itself provides a suitable default.

19.11 Oracle LOB interface

19.11.1 Introduction

The Common SQL Oracle LOB interface allows you to retrieve LOB locators and then perform operations on them. It is also possible to insert new empty LOBs.

19.11.1.1 Retrieving LOB locators

This is done by normal `select` or `query` calls where the *selections* list names one or more columns that are of a LOB type. The LOB types are BLOB, CLOB, NCLOB, BFILE and CFILE.

The returned value is a LOB locator: an opaque Lisp object on which the `ora-lob-*` APIs (that is, those functions with names beginning with "ora-lob-") can be used. This LOB locator contains a pointer to an Oracle descriptor of type OCILobLocator*. Note that there can be multiple LOB locator objects associated with the same LOB in the server, but a LOB locator uniquely identifies a LOB object.

It is possible to specify that the result object should be a stream either for input or output. Then the resulting stream (which will be of type `lob-stream`) can be used as a normal Lisp stream.

19.11.1.2 Operating on LOB locators

This is done using the `ora-lob-*` functions. Most of these functions map directly to the underlying OCILob* functions.

Note that when modifying a LOB locator, the corresponding record must be locked. See “Retrieving Lob Locators” on page 265 for details.

19.11.1.3 Inserting empty LOBs

To add a new LOB object to the database, you must insert an empty LOB. The preferred way of doing this is to use the Oracle SQL functions EMPTY_BLOB and EMPTY_CLOB, which can be called by using the pseudo operator `sql-function`, like this:

```
(sql:insert-records :into [mytable]
                         :values
                         (list "name" [sql-function 'empty_blob]))
```

This code inserts a record with "name" and an empty BLOB. It is also possible to make an empty LOB by calling `ora-lob-create-empty`, and passing the empty LOB as a value to `insert-records` or `update-records`.

19.11.2 Retrieving Lob Locators

When the selections list of a query that is used in `select`, `query`, `do-query`, `map-query`, `simple-do-query` or `loop for x being each record` contains a column of a LOB type, the results are LOB locator objects. For example, if the table definition is:

```
create table mytable {
    name varchar(200),
    image blob
}
```

Then doing

```
(sql:select [image] :from [mytable] :flatp t)
```

returns a list of LOB locators.

This example lists the size of the images in the table `mytable`:

```
(dolist (pair (sql:select [name] [image] :from [mytable]))
  (format t "~a has an image of size ~a~%" 
          (first pair) (sql:ora-lob-get-length (second pair)))
  (sql:ora-lob-free (second pair)))
```

or more efficiently

```
(sql:do-query ((name lob-locator)
                [sql:select [name] [image] :from [mytable]])
  (format t "~a has an image of size ~a~%" 
          name (sql:ora-lob-length lob-locator)))
```

Note: The lifetime of the LOB locator objects differs between the functions that return a list of objects (`select` and `query`) and the iterative functions and macros (`do-query`, `simple-do-query`, `loop` and `map-query`). The iteration functions and macros free the LOB locators that they retrieve before proceeding to the next iteration. `select` and `query` do not free the LOB locators. Each LOB locator stays alive until the application makes an explicit call to `ora-lob-free`, or until the database is closed by a call to `disconnect`.

19.11.3 Locking

When the LOB or its contents need to modified, the corresponding record must be locked (Oracle enforces this). The best way to lock a record is to pass `:for-update` when calling `select`. See `select`, page 1062 for details. For example, writing a line in the end of the log file of station number 573:

```
create table logfiles (stationid integer, logiles clob)
.. insert records ..

(sql:do-query ((log-stream)
               [select [log :output-stream] :from [logfiles]
                  :where [= [stationid] 573] :for-update t])
               (file-position log-stream :end)
               (write-line "Add this line to the log" log-stream)
               (close log-stream) ; forces the output
            )
(sql:commit)
```

Note that any call to `commit` or `rollback` on the same connection removes the lock. If you want to modify the LOB later, you must lock it again. An efficient way to achieve this is to use the special token `ROWID`, which returns the `ROWID` in the database, because this does not involve searching on the server side. For example:

19.11 Oracle LOB interface

```
(let ((lobs-list
      (sql:select [lob-field] [rowid] ; get pairs of LOB
                  :from [mytable] ; locators and ROWIDs
                  :where [some-condition])))
    ... do something ...
    ... reach a point when we want to modify one
    ... of the LOBS above and have bound one of the
    ... pairs in the variable pair.
    (sql:select [1]
                :from [mytable] ; retrieve a constant
                :where
                [= [rowid] (second pair) ; get the right record
                 :for-update t) ; lock it
    (sql:ora-lob-write-buffer (car pair) ; modify the lob
                             offset
                             amount
                             buffer)
    (sql:commit) ; also unlock everything
  )
```

19.11.4 Retrieving LOB Locators as streams

To retrieve LOB locators as streams, specify the type of retrieved object as `:input-stream` or `:output-stream` in the query. For example:

```
(sql:select [image :input-stream] :from [mytable] :flatp t)
```

returns a list of streams.

For example, to print the name of all images that start with some "magic number", that is a sequence of 4 specific bytes (#xf5 #x12 #x4e #x23):

```
(let ((array (make-array 4 :element-type '(unsigned-byte 8))))
  (sql:do-query ((name lob-stream)
                 [sql:select [name] [image :input-stream]
                           :from [mytable]])
    (when (and (read-sequence array lob-stream) 4)
      (eq (aref array 0) #xf5)
      (eq (aref array 0) #x12)
      (eq (aref array 0) #x4e)
      (eq (aref array 0) #x23))
      (print name))))
```

Closing the stream also frees the LOB object.

When using `:output-stream`, it is important to call `force-output` before trying to commit the changes, because the stream is buffered.

19.11.5 Attaching a stream to a LOB locator

It is possible to attach a stream to a LOB locator, passing the LOB locator as a `:lob-locator` argument to `(make-instance 'lob-stream ...)`. The value of the `:direction` argument must be `:input` or `:output`. By default, if the stream is closed the LOB locator is freed, unless the value of the initarg `:free-lob-locator-on-close` is passed as `nil`.

Operations via the stream can be mixed with direct operations on the LOB. However, because of the buffering, accessing the LOB contents will give non-obvious results, as other operations may not see something that was written to the stream because it is still in the stream buffer, or the stream may have already read some contents before they were overwritten. Use `force-output` or `clear-input` before accessing the LOB in other ways to avoid these problems.

It is possible to attach more than one stream to the same LOB locator, in both directions. Apart from the issue of the buffering described above, the streams can be used independently of each other. Note that if you want to close one of the streams and to continue to use the others or the LOB locator itself, you must pass `:free-lob-locator-on-close nil` when you make the stream.

The LOB locator to which a stream is attached can be found by using the reader `lob-stream-lob-locator`.

19.11.6 Interactions with foreign calls

You can define your own foreign calls and use them on the underlying OCI descriptors. For this, you need to access the OCI handles using `ora-lob-lob-locator`, and maybe `ora-lob-env-handle` and `ora-lob-svc-ctx-handle`. These accessors return foreign pointers that can be passed to foreign functions in the usual way.

When the foreign functions deal only with the data, rather than with LOB objects, use the functions `ora-lob-read-foreign-buffer`, `ora-lob-write-foreign-buffer` and `ora-lob-get-buffer`.

For example:

19.11 Oracle LOB interface

```
;;; You have a C function my_lob_processor
;;; int my_lob_processor(OCILobLocator *lob,
;;;                      OCISvcCtx *Context,
;;;                      int other_arg)

(fli:define-foreign-function my-lob-processor
  ((lob sql:p-oci-lob-locator)
   (env sql:p-oci-svc-ctx)
   (other-arg :int))
  :result-type :int)
```

Assuming you have the LOB locator in the variable *lob*, call the foreign function on it:

```
(my-lob-processor (sql:ora-lob-lob lob)
                  (sql:ora-lob-svc-ctx-handle lob)
                  36)
```

There are three handles in the LOB: the LOB descriptor itself, the environment and the context. The pointer types, the reader and the corresponding C type for each handle are shown in Table 19.3 below.

Table 19.3 Handles in the LOB locator

OCI handle	Reader	Pointer type	C type
LOB descriptor	ora-lob-lob-locator	p-oci-lob-locator Or p-oci-file	OCILobLocator*
context	ora-lob-svc-ctx-handle	p-oci-svc-ctx	OCISvcCtx*
environment	ora-lob-env-handle	p-oci-env	OCIEnv*

The pointer type **p-oci-lob-locator** is used for internal LOBs (that is, BLOB, CLOB and NCLOB). The pointer type **p-oci-file** is used for file LOBs (CFILE and BFILE). For functions that take both, the type **p-oci-lob-or-file** is defined as the union of these two types

19.11.7 Determining the type of a LOB

The function `ora-lob-internal-lob-p` returns whether it is internal (that is BLOB, CLOB or NCLOB) or not (that is BFILE or CFILE). The function `ora-lob-element-type` returns the LISP element type that best corresponds to the LOB locator. This will be one of (`unsigned-byte 8`) for BLOB and BFILE, or `base-char` or `simple-char` for CLOB, NCLOB and CFILE, depending on the charset of the LOB object.

It is possible to distinguish between CLOB and NCLOB by looking at the result of `ora-lob-char-set-form`. It returns 2 for NCLOB and 1 for CLOB.

19.11.8 Reading and writing from and to LOBs

One way of reading and writing is to use streams as described in the section “Retrieving LOB Locators as streams” on page 267. When large amounts of data are written (read) to (from) the LOB the direct interface may be useful. The direct interface is implemented by `ora-lob-read-foreign-buffer`, `ora-lob-read-buffer`, `ora-lob-write-foreign-buffer`, and `ora-lob-write-buffer`.

All the direct interfaces are more efficient if the buffer that is passed is static. That is always true for the `*-foreign-buffer` functions, but normally not true for Lisp objects. See the documentation for `make-array`, page 444. See also `ora-lob-get-buffer`.

The direct reading and writing methods can be used for "random" access, but they can also be used conveniently for efficient linear access, simply by passing `nil` as the `offset` parameter.

19.11.9 The LOB functions

Most of the LOB functions take an `errorp` argument, which is a boolean controlling what happens if an error occurs inside an OCI function. If `errorp` is true, an error is signaled. If `errorp` is false, the function returns an error object (of type `sql-database-error`).

All the LOB functions signal an error if the `lob-locator` argument given is not a LOB locator object as returned by `select` or `query`.

19.11 Oracle LOB interface

Many of the functions basically perform a call to the underlying OCI function. When the match is direct, this is mentioned in the function's manual page.

19.11.9.1 Querying functions

You can test whether a LOB locator is initialized, open or temporary with `ora-lob-locator-is-init`, `ora-lob-is-open` or `ora-lob-is-temporary`.

The predicate for internal LOBs is `ora-lob-internal-lob-p`.

`ora-lob-element-type` returns a Lisp element type corresponding to the LOB locator as described "Determining the type of a LOB" on page 270.

`ora-lob-lob-locator`, `ora-lob-env-handle` and `ora-lob-svc-ctx-handle` return foreign pointers to the various handles in the LOB mentioned in "Interactions with foreign calls" on page 268. To determine the best value for the size of a buffer use `ora-lob-get-chunk-size`.

`ora-lob-char-set-form` and `ora-lob-char-set-id` query the charset of a *lob-locator*.

The querying functions specifically for file LOBs are `ora-lob-file-exists`, `ora-lob-file-is-open` and `ora-lob-file-get-name`

You can obtain the current length of the LOB with `ora-lob-get-length`.

You can test two LOB locators for whether they point to the same LOB object with `ora-lob-is-equal`.

19.11.9.2 LOB management functions

You can create a LOB object with `ora-lob-create-empty`.

You can assign a LOB to another LOB locator with `ora-lob-assign`.

You can free a LOB locator with `ora-lob-free`.

19.11.9.3 Modifying LOBs

All the functions mentioned in this section are applicable to internal LOBs only, except `ora-lob-load-from-file`.

Before modifying a LOB, the corresponding record must be locked. See the discussion in “Locking” on page 266.

If you make several modifications to a LOB which has functional or domain indexes, it is useful to wrap several calls of modifying functions in a pair of `ora-lob-open` and `ora-lob-close`. That means that the indexes will be updated once (when `ora-lob-close` is called), which saves work. Note that after a call to `ora-lob-open`, `ora-lob-close` must be called before any call to `commit`.

To append the contents of one LOB to another, use `ora-lob-append`.

You can copy all or part of a LOB into another LOB using `ora-lob-copy`.

`ora-lob-load-from-file` loads the data from a file LOB into an (internal) LOB.

You can erase (that is, fill with the 0 byte or with Space character) all or part of a LOB using `ora-lob-erase`.

You can reduce the size of a LOB using `ora-lob-trim`.

If you need to make multiple updates to a LOB you can optionally create a transaction using `ora-lob-open` and `ora-lob-close` call. This may save work on the server side.

19.11.9.4 File operations

These functions are used to modify the properties of file LOBs.

Open and close the file associated with a file LOB using `ora-lob-file-open` and `ora-lob-file-close`.

You can close all the files associated with a file LOB locator that have been opened through the database connection with `ora-lob-file-close-all`.

You can alter the directory and/or the file name for a file LOB locator by calling `ora-lob-file-set-name`.

19.11.9.5 Direct I/O

The direct I/O functions perform input or output directly on the OCI handle, without the intervening layer of a stream. If you move large amounts of data

19.11 Oracle LOB interface

to or from the LOB, and in particular if you pass the data to or from foreign functions, the direct calls can be more efficient, and in some cases also more convenient to use. Note, however, that if you make many small modifications to the data, the `lob-stream` interface may be more efficient.

Note also that the difference in efficiency between the direct calls and the `lob-stream` interface is likely to be quite small compared to the time spent on network traffic.

If you make many modifications to a LOB, you should also consider wrapping the operations in a transaction created by a pair of calls to `ora-lob-open` and `ora-lob-close`.

You can read data from the LOB locator into a Lisp buffer or foreign buffer using `ora-lob-read-buffer` and `ora-lob-read-foreign-buffer` respectively.

Similarly `ora-lob-write-buffer` and `ora-lob-write-foreign-buffer` can be used to write buffer to a LOB.

You can obtain a buffer suitable for efficient I/O with foreign functions via `ora-lob-get-buffer`.

`ora-lob-read-into-plain-file` writes the contents of a LOB into a file.

`ora-lob-write-from-plain-file` writes the contents of a file into a LOB.

19.11.9.6 Temporary LOBs

You can create a temporary LOB with `ora-lob-create-temporary`.

You can test whether a LOB is temporary with `ora-lob-is-temporary`.

You can free a temporary LOB locator if necessary with `ora-lob-free-temporary`, though temporary LOB locators are freed automatically when the database connection is closed by `disconnect`.

19.11.9.7 Control of buffering

These functions control the internal buffering by the Oracle client: `ora-lob-enable-buffering`, `ora-lob-disable-buffering`, and `ora-lob-flush-buffer`. They have no interaction with any of the other functions above.

19.12 Using ODBC

19.12.1 Configuring unixODBC

Configure unixODBC in these files.

For the driver:

```
/etc/odbcinst.ini
```

For the datasource:

```
~/.odbc.ini
```

```
/etc/odbc.ini
```

19.12.2 Loading unixODBC

At load time do:

```
(require "odbc")
```

At runtime, Common SQL automatically loads the unixODBC module from the location in the variable `sql::*odbc-foreign-modules*`. In LispWorks for Linux this variable initially has the value `("~/usr/lib/libodbc.so")`. Therefore if, for example, the runtime machine unixODBC installed in `/usr/local/`, at runtime do:

```
(setq sql::*odbc-foreign-modules* '("~/usr/local/lib/libodbc.so"))
(sql:connect "mydatabase" :database-type :odbc)
```

19.12.3 External format for ODBC strings

On Unix, the default external format for ODBC strings is `:ascii`. On Microsoft Windows it is `win32::*multibyte-code-page-ef*`.

20

User Defined Streams

20.1 Introduction

A number of classes and functions are provided in the `stream` package that allow you to define your own input and output streams. You can use the standard Common Lisp I/O functions on these streams, and you can add methods specialized on your stream classes to provide specific implementations of other I/O functions. Note that some changes have been made to the standard I/O functions to allow for this. For example, `stream-element-type` is now a generic function. See Chapter 27, “The COMMON-LISP Package” for alterations to Common Lisp functions, and Chapter 39, “The STREAM Package” for more details on the API for user defined streams.

20.2 An illustrative example of user defined streams

In this chapter an example is provided to illustrate the main features of the `stream` package. In this example a stream class is defined to provide a wrapper for `file-stream` which uses the Unicode Line Separator instead of the usual ASCII CR/LF combination to mark the end of lines in the file. Methods are then defined, specializing on the user defined stream class to ensure that it handles reading from and writing to a file correctly.

20.2.1 Defining a new stream class

Streams can be capable of input or output (or both), and may deal with characters or with binary elements. The `stream` package provides a number of stream classes with different capabilities from which user defined streams can inherit. In our example the stream must be capable of input and output, and must read characters. The following code defines our stream class appropriately:

```
(defclass unicode-ls-stream
  (stream:fundamental-character-input-stream
   stream:fundamental-character-output-stream)
  ((file-stream :initform nil
                :initarg :file-stream
                :accessor ls-stream-file-stream)))
```

The new class, `unicode-ls-stream`, has `fundamental-character-input-stream` and `fundamental-character-output-stream` as its superclasses, which means it inherits the relevant default character I/O methods. We shall be overriding some of these with more relevant and efficient implementations later.

Note that we have also provided a `file-stream` slot. When making an instance of `unicode-ls-stream` we can create an instance of a Common Lisp file stream in this slot. This allows us to use the Common Lisp file stream functionality for reading from and writing to a file.

20.2.2 Recognizing the stream element type

We know that the stream will read from a file using `file-stream` functionality and that the stream element type will be `simple-char`. The following defines a method on `stream-element-type` to return the correct element type.

```
(defmethod stream-element-type ((stream unicode-ls-stream))
  'simple-char)
```

20.2.3 Stream directionality

Streams can be defined for input only, output only, or both. In our example, the `unicode-ls-stream` class needs to be able to read from a file and write to a file, and we therefore defined it to inherit from an input and an output

stream class. We could have defined disjoint classes instead, one inheriting from `fundamental-character-input-stream` and the other from `fundamental-character-output-stream`. This would have allowed us to rely on the default methods for the direction predicates.

However, given that we have defined one bi-directional stream class, we must define our own methods for the direction predicates. To allow this, the Common Lisp predicates `input-stream-p` and `output-stream-p` are implemented as generic functions.

```
(defmethod input-stream-p ((stream unicode-ls-stream))
  (input-stream-p (ls-stream-file-stream stream)))

(defmethod output-stream-p ((stream unicode-ls-stream))
  (output-stream-p (ls-stream-file-stream stream)))
```

The above code allows us to “trampoline” the correct direction predicate functionality from `file-stream`, using the `ls-stream-file-stream` accessor we defined previously.

20.2.4 Stream input

The following method for `stream-read-char` reads a character from the stream. If the character read is a `#\Line-Separator`, then the method returns `#\Newline`, otherwise the character read is returned. `stream-read-char` returns `:eof` at the end of the file.

```
(defmethod stream:stream-read-char ((stream unicode-ls-stream))
  (let ((char (read-char (ls-stream-file-stream stream)
                        nil :eof)))
    (if (eq char #\Line-Separator)
        #\Newline
        char)))
```

There is no need to define a new method for `stream-read-line` as the default method uses `stream-read-char` repeatedly to read a line, and our implementation of `stream-read-char` ensures that this will work.

We also need to make sure that if a `#\Newline` is unread, it is unread as a `#\Line-Separator`. The following method for `stream-unread-char` uses the Common Lisp file stream function `unread-char` to achieve this.

```
(defmethod stream:stream-unread-char ((stream unicode-ls-stream)
                                       char)
  (unread-char (if (eq char #\Newline) #\Line-Separator char)
               (ls-stream-file-stream stream)))
```

Finally, although the default methods for `stream-listen` and `stream-clear-input` would work for our stream, it is faster to use the functions provided by `file-stream`, again using our accessor `ls-stream-file-stream`.

```
(defmethod stream:stream-listen ((stream unicode-ls-stream))
  (listen (ls-stream-file-stream stream)))

(defmethod stream:stream-clear-input ((stream unicode-ls-stream))
  (clear-input (ls-stream-file-stream stream)))
```

20.2.5 Stream output

The following method for `stream-write-char` uses `write-char` to write a character to the stream. If the character written to `unicode-ls-stream` is a `#\Newline`, then the method writes a `#\Line-Separator` to the file stream.

```
(defmethod stream:stream-write-char ((stream unicode-ls-stream)
                                       char)
  (write-char (if (eq char #\Newline)
                 #\Line-Separator
                 char)
              (ls-stream-file-stream stream)))
```

The default method for `stream-write-string` calls `stream-write-char` repeatedly to write a string to the stream. However, the following is a more efficient implementation for our stream.

```
(defmethod stream:stream-write-string ((stream unicode-ls-stream)
                                         string &optional (start 0)
                                         (end (length string)))
  (loop with i = start
        until (>= i end)
        do (let* ((newline (position #\Newline
                                      string :start i :end end))
                  (this-end (or newline end)))
            (write-string string (ls-stream-file-stream stream)
                         :start i :end this-end)
            (incf i this-end)
            (when newline
              (stream:stream-terpri stream)
              (incf i)))
        finally (return string)))
```

We do not need to define our own method for `stream-terpri`, as the default uses `stream-write-char`, and therefore works appropriately.

To be useful, the `stream-line-column` and `stream-start-line-p` generic functions need to know the number of characters preceding a `#\Line-Separator`. However, since the LispWorks file stream records line position only by `\Newline` characters, this information is not available. Hence we define the two generic functions to return `nil`:

```
(defmethod stream:stream-line-column
  ((stream unicode-ls-stream))
  nil)

(defmethod stream:stream-start-line-p
  ((stream unicode-ls-stream))
  nil)
```

Finally, the methods for `stream-force-output`, `stream-finish-output` and `stream-clear-output` are “trampolined” from the standard `force-output`, `finish-output` and `clear-output` functions.

```
(defmethod stream:stream-force-output ((stream
                                         unicode-ls-stream))
  (force-output (ls-stream-file-stream stream)))

(defmethod stream:stream-finish-output ((stream
                                         unicode-ls-stream))
  (finish-output (ls-stream-file-stream stream)))
```

```
(defmethod stream:stream-clear-output ((stream
                                         unicode-ls-stream))
  (clear-output (ls-stream-file-stream stream)))
```

20.2.6 Instantiating the stream

Now that the stream class has been defined, and all the methods relevant to it have been set up, we can create an instance of our user defined stream to test it. The following function takes a filename and optionally a stream direction as its arguments and makes an instance of `unicode-ls-stream`. It ensures that the `file-stream` slot of the stream contains a Common Lisp `file-stream` capable of reading from or writing to a file given by the filename argument.

```
(defun open-unicode-ls-file (filename &key (direction :input))
  (make-instance 'unicode-ls-stream :file-stream
    (open filename
      :direction direction
      :external-format :unicode
      :element-type 'simple-char)))
```

The following macro uses `open-unicode-ls-stream` in a similar manner to the Common Lisp macro `with-open-file`:

```
(defmacro with-open-unicode-ls-file ((var filename
                                         &key (direction :input))
                                         &body body)
  `(let ((,var (open-unicode-ls-file ,filename
                                         :direction ,direction)))
    (unwind-protect
      (progn ,@body)
      (close ,var)))
```

We now have the required functions and macros to test our user defined stream. The following code uses `config.sys` as a source of input to an instance of our stream, and outputs it to the file `unicode-ls.out`, changing all occurrences of `#\Newline` to `#\Line-Separator` in the process.

```
(with-open-unicode-ls-file (ss "C:\\unicode-ls.out"
                               :direction :output)
  (write-line "-- Encoding: Unicode; --" ss)
  (with-open-file (ii "C:\\config.sys") ; Don't edit this file!
    (loop with line = nil
          while (setf line (read-line ii nil nil))
          do (write-line line ss))))
```

After running the above code, if you load the file `C:\\unicode-ls.out` into an editor (for example, a LispWorks editor), you can see the line separator used instead of CR/LF. Most editors do not yet recognize the Unicode Line Separator character yet. In some editors it appears as a blank glyph, whereas in the LispWorks editor it appears as `<2028>`. In LispWorks you can use `Alt+X What Cursor Position` or `Ctrl+X =` to identify the unprintable characters.

You can also use the follow code to print out the contents of the new file line by line.

```
(with-open-unicode-ls-file (ss "C:\\unicode-ls.out")
  (loop while (when-let (line (read-line ss nil nil))
            (write-line line))))
```

21

TCP/IP socket communication and SSL

The interface for using TCP/IP sockets in LispWorks is in the "`comm`" module, and all the symbols are in the `comm` package, and documented in the "The COMM Package" on page 355.

To use it you need to require the module by

```
(require "comm")
```

21.1 Running a server that accepts connections

The function `start-up-server` starts a new thread which:

1. Creates a socket, then
2. Prepares it (that is, binds it to the address and port and does various other settings) and then
3. Waits for connections to it ("accepting connections")

When a connection is made, a programmer-supplied function is called with the new socket. Typically this function creates a stream of type `socket-stream` with this socket, and then uses the stream for communication through the socket using standard Common Lisp I/O functions.

21.2 Connecting to a server

The function `open-tcp-stream` connects to a server and returns a stream (of type `socket-stream`). The stream is then used for communication through the socket using the standard Lisp I/O functions.

`connect-to-tcp-server` can also be used, especially if you want to subclass `socket-stream`.

21.2.1 Examples

For examples illustrating simple write and read on a socket, see these files in `lib/6-1-0-0/examples`

```
capi/applications/chat.lisp
capi/applications/chat-client.lisp
```

21.3 Information about IP addresses

The function `get-host-entry` can be used to find the address of a domain name or the domain name of an address. It can also used to find multiple addresses and aliases.

`get-socket-address`, `get-socket-peer-address` and `socket-stream-address` and `socket-stream-peer-address` can be used to find the IP address of opened sockets.

21.4 Waiting on a socket stream

The function `wait-for-input-streams` and `wait-for-input-streams-returning-first` are a convenient interface for waiting for input from socket streams. The standard I/O functions (`cl:read`, `cl:read-char` and so on) can also wait properly. You can also use `process-wait` and similar functions with `cl:listen` in the `wait-function`, but you will need to use `with-noticed-socket-stream`.

21.5 Special considerations

The host machine must be configured properly to handle IPv6 for the Lisp-Works interface to work with IPv6.

It is likely that all new machines can use IPv6.

21.5.1 IPv6 on Mac OS X

IPv6 addresses work properly on Mac OS X 10.6.

21.5.2 IPv6 on Windows XP

By default IPv6 addresses do not work on Microsoft Windows XP. To make it work on Windows XP, install the interface by executing this command in a console, as an administrator user:

```
netsh interface ipv6 install
```

This should not be needed on later versions of Microsoft Windows. Search for `netsh` on technet.microsoft.com for more information.

21.6 Socket Stream SSL interface

The Socket Stream SSL interface allows you to use Secure Socket Layer (SSL) with Lisp objects of type `socket-stream`.

The interface is based on the OpenSSL code, and most of it is simply an FLI interface to OpenSSL functions. The main LispWorks specific code is the way OpenSSL is integrated with `socket-stream`.

The Socket Stream SSL interface is in the "`comm`" module, so to load it you evaluate

```
(require "comm")
```

Note: In this section we assume that the current package uses the `comm` package. That is, `comm` package symbols may not be qualified explicitly.

21.6.1 Creating a stream with SSL

There are three ways to make a `socket-stream` with SSL processing:

- Call `(make-instance 'socket-stream :ssl-ctx ...)`
- Call `(open-tcp-stream ... :ssl-ctx ...)`
- Call `attach-ssl` on a `socket-stream`.

For example:

```
(open-tcp-stream some-url 443 :ssl-ctx t)
```

21.6.2 SSL-CTX and SSL objects

When the value of the `:ssl-ctx` argument is a symbol, LispWorks automatically creates an SSL_CTX object and an SSL object and uses them. If you need to configure these objects, you can access them by the following methods:

- When passing `:ssl-ctx` or when calling `attach-ssl` (as described above) also pass `:ctx-configure-callback` and `:ssl-configure-callback`.
- Use the accessors `socket-stream-ssl` and `socket-stream-ctx`.
- Make your own SSL-CTX or SSL objects and pass them as the `ssl-ctx` argument.

21.6.3 OpenSSL interface

The configuration interface contains mostly FLI function definitions that map directly to OpenSSL calls. See below for a list of those provided.

There are also some functions to make common cases simpler. These are `read-dhparams`, `pem-read`, `set-ssl-ctx-options`, `set-ssl-ctx-password-callback`, and `set-ssl-ctx-dh`.

21.6.3.1 OpenSSL constants

The Lisp constants `SSL_FILETYPE_ASN1` and `SSL_FILETYPE_PEM` representing file types are provided.

21.6.3.2 Naming conventions for direct OpenSSL calls

This section describes the mapping between OpenSSL function names and the corresponding Lisp names.

21.6.3.3 Mapping C names to Lisp names

For functions that map directly to OpenSSL calls, the convention is to create the LISP name from the C name by replacing underscores by hyphens.

21.6.3.4 Mapping Lisp names to C names

To find the C name from the LISP function name:

1. the hyphens need to be replaced by underscores, and
2. the initial SSL or SSL_CTX has to be in uppercase, and
3. the rest has to be lowercase, except that
4. the following phrases are cased specially, like this: "RSAPrivateKey", "DSH", "ASN1", "CA", "PrivateKey"

21.6.4 Direct calls to OpenSSL

The following functions map directly to the OpenSSL functions. Check the OpenSSL documentation for details.

Where an OpenSSL function takes an SSL* or SSL_CTX*, the Lisp function's argument must be a foreign pointer of type `ssl-pointer`, `ssl-ctx-pointer` or `ssl-cipher-pointer`. Where an OpenSSL function takes a `char*` or `int`, the Lisp function's argument must be a string or integer. Where an OpenSSL function takes other kinds of pointers, the Lisp function's argument must be a foreign pointer. The return values are integers or foreign pointers unless stated otherwise.

If an error occurs in one of these functions, an error code is returned. They do not signal any Common Lisp conditions and so you should check the return value carefully.

Table 21.1 Direct calls to OpenSSL

Lisp function	Return values
<code>ssl-add-client-ca</code>	

Table 21.1 Direct calls to OpenSSL

Lisp function	Return values
<code>ssl-cipher-get-bits</code>	First value is number of bits the cipher actually uses. Second value is number of bits the algorithm of the cipher can use (which may be higher).
<code>ssl-cipher-get-name</code>	string. e.g. "DHE-RSA-AES256-SHA"
<code>ssl-cipher-get-version</code>	string. e.g. "TLSv1/SSLv3"
<code>ssl-clear-num-renegotiations</code>	
<code>ssl-ctrl</code>	
<code>ssl-ctx-add-client-ca</code>	
<code>ssl-ctx-add-extra-chain-cert</code>	
<code>ssl-ctx-ctrl</code>	
<code>ssl-ctx-get-max-cert-list</code>	
<code>ssl-ctx-get-mode</code>	
<code>ssl-ctx-get-options</code>	
<code>ssl-ctx-get-read-ahead</code>	
<code>ssl-ctx-get-verify-mode</code>	integer
<code>ssl-ctx-load-verify-locations</code>	
<code>ssl-ctx-need-tmp-rsa</code>	
<code>ssl-ctx-sess-set-cache-size</code>	
<code>ssl-ctx-sess-get-cache-size</code>	
<code>ssl-ctx-sess-set-cache-mode</code>	
<code>ssl-ctx-sess-get-cache-mode</code>	
<code>ssl-ctx-set-client-ca-list</code>	

Table 21.1 Direct calls to OpenSSL

Lisp function	Return values
<code>ssl-ctx-set-max-cert-list</code>	
<code>ssl-ctx-set-mode</code>	
<code>ssl-ctx-set-options</code>	
<code>ssl-ctx-set-read-ahead</code>	
<code>ssl-ctx-set-tmp-rsa</code>	
<code>ssl-ctx-set-tmp-dh</code>	
<code>ssl-ctx-use-certificate-chain-file</code>	
<code>ssl-ctx-use-certificate-file</code>	
<code>ssl-ctx-use-privatekey-file</code>	
<code>ssl-ctx-use-rsaprivatekey-file</code>	
<code>ssl-get-current-cipher</code>	<code>ssl-cipher-pointer</code> Can be a null pointer.
<code>ssl-get-max-cert-list</code>	
<code>ssl-get-mode</code>	
<code>ssl-get-options</code>	
<code>ssl-get-verify-mode</code>	integer
<code>ssl-get-version</code>	string "TLSv1", "SSLv2" or "SSLv3"
<code>ssl-load-client-ca-file</code>	
<code>ssl-need-tmp-rsa</code>	
<code>ssl-num-renegotiations</code>	
<code>ssl-session-reused</code>	
<code>ssl-set-accept-state</code>	None

Table 21.1 Direct calls to OpenSSL

Lisp function	Return values
<code>ssl-set-client-ca-list</code>	
<code>ssl-set-connect-state</code>	None
<code>ssl-set-max-cert-list</code>	
<code>ssl-set-mode</code>	
<code>ssl-set-options</code>	
<code>ssl-set-tmp-rsa</code>	
<code>ssl-set-tmp-dh</code>	
<code>ssl-total-renegotiations</code>	
<code>ssl-use-certificate-file</code>	
<code>ssl-use-rsaprivatekey-file</code>	
<code>ssl-use-privatekey-file</code>	

If you need OpenSSL functionality that is not provided here, you can define your own foreign functions via the LispWorks Foreign Language Interface.

If you do this, an important point to note is that on Microsoft Windows, the `:calling-convention` must be `:cdecl` (it defaults to `:stdcall`). If using OpenSSL suddenly causes mysterious crashes, the `calling-convention` in your foreign function definitions is the first thing to check.

21.6.5 Socket Stream SSL keyword arguments

The keyword arguments `:ssl-ctx`, `:ssl-side`, `:ctx-configure-callback` and `:ssl-configure-callback` can be passed to create and configure socket streams with SSL processing. The various methods for creating and configuring SSL streams accept these keyword arguments as shown in Table 21.2, page 291.

Table 21.2 SSL configuration keywords

	<code>:ssl-ctx</code>	<code>:ssl-side</code>	<code>:ctx-configure-callback</code>	<code>:ssl-configure-callback</code>
<code>socket-stream make-instance</code>	Yes	Yes	Yes	Yes
<code>open-tcp- stream</code>	Yes	No	Yes	Yes
<code>attach-ssl</code>	Yes	Yes	Yes	Yes
<code>make-ssl-ctx</code>	Yes	Yes	No	No

(`make-instance 'socket-stream ...`) and `open-tcp-stream`, when `ssl-ctx` is non-nil, call `attach-ssl` and pass it all the arguments.

`:ssl-ctx` specifies that SSL should be used, and also specifies the SSL_CTX object to use. See the OpenSSL manual entry for `SSL_CTX_new` for details of making a SSL_CTX. The value of `ssl-ctx` can be:

A symbol

Together with `ssl-side`, this symbol specifies which protocol to use. `ssl-ctx` can be one of:

1) `t` or `:default`, meaning use the default. Currently this is the same as `:v23`.

2) One of `:v2`, `:v3`, `:v23` or `:tls-v1`. These are mapped to the `SSLv2_*`, `SSLv3_*`, `SSLv23_*`, `TLSv1_*` methods.

LispWorks makes a new SSL_CTX object and uses it and frees it when the stream is closed. `make-instance`, `attach-ssl` and `open-tcp-stream` also make an SSL object, use it and free it when the stream is closed.

A foreign pointer of type `ssl-ctx-pointer`

This corresponds to the C type SSL_CTX*. This is used and is not freed when the stream is closed. `make-instance`, `attach-ssl` and `open-tcp-stream` also make an SSL object, use it and free it when the stream is closed. The foreign pointer maybe a result of a call to `make-ssl-ctx`, but it can also be a result of your code, provided that it points to a valid SSL_CTX and has the type `ssl-ctx-pointer`.

A foreign pointer of type `ssl-pointer`

This corresponds to the C type SSL*. This specifies the SSL to use in `make-instance`, `attach-ssl` and `open-tcp-stream`. This maybe a result of a call to `ssl-new`, but can also be a result of your code, provided that it points to a valid SSL object and has the type `ssl-pointer`. The SSL is used and is not freed when the stream is closed.

When you pass a `ssl-ctx-pointer` or a `ssl-pointer` foreign pointer, these must have already been set up correctly.

`:ssl-side` specifies which side the stream is. The value `ssl-side` can be one of `:client`, `:server` OR `:both`. `open-tcp-stream` does not take this keyword and always uses `:client`. For the other calls this argument defaults to `:server`. The value of `ssl-side` is used in two cases:

When a new SSL_CTX object is created, it is used to select the method:

```
:client => *_client_method
:server => *_server_method
:both  => *_method
```

When a new SSL object is created, when `ssl-side` is either `:client` or `:server`, LispWorks calls `ssl-set-connect-state` or `ssl-set-accept-state` respectively.

If the value of `ssl-ctx` is a `ssl-pointer`, `ssl-side` is ignored.

`:ctx-configure-callback` specifies a callback, a function which takes a foreign pointer of type `ssl-ctx-pointer`. This is called immediately after a new

`SSL_CTX` is created. If the value of `ssl-ctx` is not a symbol, `ctx-configure-callback` is ignored.

`:ssl-configure-callback` specifies a callback, a function which takes a foreign pointer of type `ssl-pointer`. This is called immediately after a new SSL is created. If the value of `ssl-ctx` is not a `ssl-pointer`, `ssl-configure-callback` is ignored.

21.6.6 Attaching SSL to an existing socket-stream

You can attach SSL to an existing `socket-stream` by calling `attach-ssl` on the stream. `attach-ssl` ensures the OpenSSL library is loaded and seeds the Pseudo Random Number Generator (PRNG). The `socket-stream` SSL keyword arguments are processed by `attach-ssl` as described in “Socket Stream SSL keyword arguments” on page 290.

Detach SSL from a `socket-stream` and shut down the SSL with `detach-ssl`.

For full descriptions see `attach-ssl`, page 355 and `detach-ssl`, page 360.

21.6.7 Using SSL objects directly

The C objects SSL and SSL_CTX are represented in LispWorks by foreign pointers with type `ssl-pointer` and `ssl-ctx-pointer`, which correspond to the C types `SSL*` and `SSL_CTX*`. These foreign types should be used for any foreign function that takes or returns these C types, and must be used when passing a foreign pointer as the value of the `:ssl-ctx` argument.

Making SSL objects is a way of getting access to them to perform configuration, but, especially in the case of the SSL_CTX, it is a useful way to avoid repeated calls to the configuration routines which may be time consuming. For example, if we have defined a function `configure-a-ctx`, and we want to read once every 60 seconds from some URL, we can write:

```
(loop (with-open-stream
      (str (comm:open-tcp-stream some-url 443 :ssl-ctx t
                           :ctx-configure-callback
                           'configure-a-ctx))
        (read-something str))
      (sleep 60))
```

This will cause `configure-a-ctx` to be called each time. If it is expensive, we can call it only once by changing the code to:

```
(let ((ctx (comm:make-ssl-ctx :ssl-side :client)))
  (configure-a-ctx ctx)
  (loop (with-open-stream
          (str (comm:open-tcp-stream some-url 443 :ssl-ctx ctx))
          (read-something str))
        (sleep 60))
    (ssl-ctx-free ctx)))
```

The SSL objects could be made either by `make-ssl-ctx` or `ssl-new` or by user code that calls the C functions `SSL_CTX_new` and `SSL_new`. `destroy-ssl-ctx` frees the `SSL_CTX` object. To free an SSL object you would call `destroy-ssl`. See the manual entries for full descriptions of these functions.

21.6.8 Initialization

All the functions that make a `SSL_CTX` first call `ensure-ssl`, so normally you do not need to initialize the library. If your code makes a `SSL_CTX` itself (that is, not by calling any of the LispWorks interface functions), it needs to initialize the library first. Normally that should be done by an explicit call to `ensure-ssl`, which loads the SSL library and calls `SSL_library_init` and `SSL_load_error_strings`, and also does some LispWorks specific initializations. If your code must do the initialization, `ensure-ssl` should still be called with the argument `:already-done t`, which tells it that the library is already loaded and initialized.

21.6.9 Obtaining and installing the OpenSSL library

At the time of writing, OpenSSL is available as shown in Table 21.3:

Table 21.3 OpenSSL availability

Operating System	Availability of OpenSSL
Linux	Installed by default on most 32-bit and 64-bit distributions
Windows	32-bit and 64-bit libraries are available at www.slproweb.com/products/Win32OpenSSL.html

Table 21.3 OpenSSL availability

Operating System	Availability of OpenSSL
Mac OS X	32-bit and 64-bit libraries are installed by default.
FreeBSD	Installed by default
x86/x64 Solaris	Installed by default
SPARC Solaris	Installed by default on Solaris 10. For other verisons, see the freeware from Sun at sunfreeware.com for both 32-bit and 64-bit.

21.6.9.1 Installing the OpenSSL library on Solaris

After installing (with pkgadd) you need to put the shared libraries `libcrypto.so` and `libssl.so` on the loader path. By default these are installed in `/usr/local/ssl/lib`.

To add the libraries to the loader path, either

- Add `/usr/local/ssl/lib` to the environment variable `LD_LIBRARY_PATH`, or
- Create links from `/usr/lib`.

21.6.9.2 Loading the OpenSSL libraries

Since OpenSSL is not a standard on all machines yet, the location of the library or libraries varies. By default, `ensure-ssl` loads libraries as shown in Table 21.4, page 295.

Table 21.4 Loading the OpenSSL libraries

Operating System	Libraries
Linux	<code>-lssl</code>
Windows	<code>libeay32.dll</code> <code>libssl32.dll</code>

Table 21.4 Loading the OpenSSL libraries

Operating System	Libraries
Solaris	<code>-lssl</code>
Mac OS X	<code>-lssl</code>
Others	<code>nil</code>

On machines where the path is unknown or is incorrect, you must set the path. Do this by calling `set-ssl-library-path`, or by passing the path as the *library-path* argument to `ensure-ssl`.

21.6.10 Errors in SSL

If there are errors inside SSL, LispWorks will signal an error of type `ssl-condition`, which is a subclass of `socket-error`.

The condition can be one of the types `ssl-x509-lookup`, `ssl-closed`, `ssl-error` and `ssl-failure`. See the manual pages for details of these condition classes.

21.6.11 Examples of using the socket stream SSL interface

See these example files in `lib/6-1-0-0/examples`

```
ssl/ssl-client.lisp
ssl/ssl-server.lisp
ssl/ssl-certificates.lisp
```

22

Internationalization

22.1 Introduction

LispWorks uses Unicode (UCS-2 encoding) internally in its representation of `character` objects. All Unicode characters can be represented in strings, though 8-bit string types are also provided for efficiency when characters beyond the Latin-1 range are not needed. Character and string data can be input and output in various encodings (external formats).

22.2 Character and String types

22.2.1 Character types

The following subtypes of character are defined:

- `base-char` simple characters with `char-code` less than
`base-char-code-limit` (256).
- `simple-char` simple characters with `char-code` less than
`char-code-limit` (65536).
- `character` All characters including non-simple characters (that is,
with non-null bits attributes).

22.2.2 Character Syntax

All simple characters have names that consist of `u+` followed by the code of the character in hexadecimal, for example `#\U+764F` is (`code-char #x764F`).

Additionally, Latin-1 characters have names derived from the ISO10646 name, for example:

```
(char-name (code-char 190))
=>
"Vulgar-Fraction-Three-Quarters"
```

Names are also provided for space characters:

```
(name-char "Ideographic-Space")
=>
#\Ideographic-Space
```

If required, the bits attributes names can be prepended as usual:

```
#\ctrl-ideographic-space
=>
#\Control-Ideographic-Space
```

22.2.3 String types

String types are supplied which are capable of holding each of the character types mentioned above. The following string types are defined:

<code>base-string</code>	holds any <code>base-char</code>
<code>text-string</code>	holds any <code>simple-char</code>
<code>augmented-string</code>	holds any <code>character</code> .

In particular, `text-string` is the type that can hold all characters used in texts. The types above include non-simple strings - those which are displaced, adjustable or with a fill-pointer.

The Common Lisp type `string` itself is dependent on the value of `*default-character-element-type*` according to the rules for string construction described in “String Construction” on page 300. For example:

```

CL-USER 1 > (set-default-character-element-type 'base-char)
BASE-CHAR

CL-USER 2 > (coerce (list #\Ideographic-Space) 'string)

Error: #\Ideographic-Space is not of type BASE-CHAR.
1 (abort) Return to level 0.
2 Return to top loop level 0.

Type :b for backtrace or :c <option number> to proceed.
Type :bug-form "<subject>" for a bug report template or :? for
other options.

CL-USER 3 : 1 > :a

CL-USER 4 > (set-default-character-element-type 'simple-char)
SIMPLE-CHAR

CL-USER 5 > (coerce (list #\Ideographic-Space) 'string)
" "

```

The following types are subtypes of `simple-string`. Note that in the names of the string types, 'simple' refers to the string object and does not mean that the string's elements are `simple-chars`.

<code>simple-base-string</code>	holds any <code>base-char</code>
<code>simple-text-string</code>	holds any <code>simple-char</code>
<code>simple-augmented-string</code>	holds any character.

The Common Lisp type `simple-string` itself is dependent on the value of `*default-character-element-type*` according to the rules for string construction described in "String Construction" on page 300.

22.2.3.1 String types at runtime

The type `string` (and hence `simple-string`) is defined by ANSI Common Lisp to be a union of all the character array types. This makes a call like

```
(coerce s 'simple-string)
```

ambiguous because it needs to select a concrete type (such as `simple-base-string` or `simple-text-string`).

When LispWorks is running with `*default-character-element-type*` set to `base-char`, it expects that you will want strings with element type `base-char`, so functions like `coerce` treat references to `simple-string` as if they were `(simple-array base-char *)`.

If you call `set-default-character-element-type` with a larger character type, then `simple-string` becomes a union of the array types that are sub-types of that character type.

22.2.3.2 String types at compile time

The compiler always does type inferencing for `simple-string` as if `*default-character-element-type*` was set to `character`.

For example, when you declare something to be of type `simple-string`, the compiler will never treat it as `simple-base-string`. Therefore calls like

```
(schar (the simple-string x) 0)
```

will work whether `x` is a `simple-base-string`, `simple-text-string` or `simple-augmented-string`.

22.3 String accessors

`schar` works on any simple string object. However, for efficient string access when a simple string type is known, the following specialized accessors are provided:

<code>sbchar</code>	for <code>simple-base-string</code> .
<code>stchar</code>	for <code>simple-text-string</code> .

22.4 String Construction

LispWorks constructs strings of a suitable type where sufficient information is available. Failing that, strings are constructed of type according to the value of `*default-character-element-type*`.

22.4.1 Default string construction

If the value of `*default-character-element-type*` is `base-char` then:

```
(make-string 3)
```

returns a `simple-base-string` and

```
(coerce sequence 'simple-string)
```

attempts to construct a `simple-base-string`. This will signal an error if any element of `sequence` is not a `base-char`.

If the value of `*default-character-element-type*` is `simple-char` then

```
(make-string 3)
```

returns a `simple-text-string` and

```
(coerce sequence 'simple-string)
```

attempts to construct a `simple-text-string`. This will signal an error if any element of `sequence` is not a `simple-char`.

Other string constructors also take their default from `*default-character-element-type*`. For instance, `with-output-to-string` and `make-string-output-stream` will construct a stream with element type determined by this variable and generate a string of the same element type.

Also the string reader will always construct a string of type determined by `*default-character-element-type*`, unless it sees a character of a larger type, in which case a suitable string is constructed. For example:

```
CL-USER 1 > (set-default-character-element-type 'simple-char)
SIMPLE-CHAR
```

```
CL-USER 2 > (type-of "ABC")
SIMPLE-TEXT-STRING
```

Compatibility note: In LispWorks 6.0 and earlier versions, the string reader would not always obey `*default-character-element-type*`, due to a bug.

22.4.2 String construction with known type

The parameter `*default-character-element-type*` merely provides the default behavior. If enough information is supplied, then a string of suitable type is constructed. For instance, the form:

```
(make-string 3 :initial-element #\Ideographic-Space)
```

constructs a string of a type that can hold its elements, regardless of the value of `*default-character-element-type*`.

22.4.3 Controlling string construction

The initial value of `*default-character-element-type*` is `base-char`, to avoid programs that only require 8-bit strings needlessly creating larger string objects. If your application uses Unicode characters beyond the Latin-1 range (characters of type `extended-char`) then you should consider which of the following two approaches to use:

- Ensure that all strings which may hold `extended-chars` are constructed explicitly with the appropriate type. This is the conservative approach, allowing you to avoid allocation of 16-bit strings where these are not required. Note that you can use the specialized accessors such as `stchar` for strings of type `simple-text-string`.
- Change the default so that by default 16-bit strings are allocated. Do this by:

```
(set-default-character-element-type 'simple-char)
```

Bear in mind that this is a global setting which affects default string construction for the entire system. It could be called from a user interface, depending on whether the user needs to handle `extended-chars`.

Note: Do not attempt to bind or set directly the variable `*default-character-element-type*`. Instead, call `set-default-character-element-type`.

22.4.4 String construction on Windows systems

When LispWorks for Windows starts up on a OS with a non-Latin-1 code page, it calls

```
(set-default-character-element-type 'simple-char)
```

so that by default, newly constructed strings can contain the data likely to be returned from the OS or user input.

If you know your string only needs to contain 8-bit data, then you can create it explicitly with element type `base-char`.

Conversely if you know that a string may need to contain 16-bit data even on a Latin-1 code page system, then you should create it explicitly with element-type `simple-char`.

22.5 External Formats

External formats are two-way translations from Lisp's internal encoding to an external encoding. They can be used in file I/O, and in passing and receiving string data in foreign function calls.

An external format is named in LispWorks by an *external format specification* (*ef-spec*). An ef-spec is a symbol naming the external format, or a list with such a name as its first element followed by parameter/value pairs.

LispWorks has a number of predefined external formats:

`win32:code-page`

The Windows code page with identifier given by the `:id` parameter. Implemented only on Windows.

`:latin-1` ISO8859-1.

`:latin-1-terminal`

As Latin-1, except that if a non-Latin-1 character is output, it is written as <xxxx> where xxxx is the hexadecimal character code and does not signal error.

`:latin-1-safe`

As Latin-1, except that if a non-Latin-1 character is output, it is written as ? and does not signal error.

`:macos-roman`

The Mac OS Roman encoding.

`:ascii` ASCII.

<code>:unicode</code>	The UCS-2 encoding of Unicode. The parameter <code>:little-endian</code> defaults to the endianness of the platform.
<code>:utf-8</code>	The UTF-8 encoding of Unicode.
<code>:jis</code>	JIS. The encoding data is read from a file <code>Uni2JIS</code> and is pre-built into LispWorks.
<code>:euc-jp</code>	EUC-JP. The encoding data is read from a file <code>Uni2JIS</code> and is pre-built into LispWorks.
<code>:sjis</code>	Shift JIS.
<code>:windows-cp936</code>	Windows code page 936. The encoding data is read from a file <code>windows-936-2000.ucm</code> and is pre-built into LispWorks.
<code>:gbk</code>	A synonym for <code>:windows-cp936</code> .

Note: `windows-936-2000.ucm` is provided by way of documentation in the directory `lib/6-1-0-0/etc/`. It is not read at runtime.

Note: `Uni2JIS` is provided by way of documentation in the directory `lib/6-1-0-0/etc/`. It is also used at runtime by the function `char-name`.

22.6 External Formats and File Streams

The `:external-format` argument of `open` and related functions should be an ef-spec, where the name can be `:default`. The symbol `:default` is the default value.

If you know the format of the data when doing file I/O, you should definitely specify *external-format* explicitly, in the ef-spec syntax described in this section.

22.6.1 Complete external format ef-specs

An ef-spec is "complete" if and only if the name is not `:default` and the parameters include `:eol-style`.

All external formats have an `:eol-style` parameter. If *eol-style* is not explicit in an ef-spec a default is used. The allowed values are

<code>:lf</code>	This is the default on Unix/Linux/FreeBSD/Mac OS X systems, meaning that lines are terminated by Linefeed.
<code>:crlf</code>	This is the default on Windows, meaning that lines are terminated by Carriage-Return followed by Linefeed.
<code>:cr</code>	Lines are terminated by Carriage-Return.

22.6.2 Using complete external formats

If `open` or `with-open-file` gets a complete `:external-format` argument then, it is used as is. For example, this form opens an ASCII linefeed-terminated stream:

```
(with-open-file (ss "C:/temp/ascii-lf"
                     :direction :output
                     :external-format
                     '(:ascii :eol-style :lf))
  (stream-external-format ss))
=>
(:ASCII :EOL-STYLE :LF)
```

If you know the encoding of a file you are opening, then you should pass the appropriate `:external-format` argument.

22.6.3 Guessing the external format

If `open` or `with-open-file` gets a non-complete `:external-format` argument `ef-spec` then the system decides which external format to use by calling the function `guess-external-format`.

The default behavior of `guess-external-format` is as follows:

- When `ef-spec`'s name is `:default`, this finds a match based on the file-name; or (if that fails), looks in the Emacs-style (-*) attribute line for an option called ENCODING or EXTERNAL-FORMAT; or (if that fails), chooses from amongst likely encodings by analysing the bytes near the start of the file, or (if that fails) uses a default encoding. Otherwise `ef-spec`'s name is assumed to name an encoding and this encoding is used.
- When `ef-spec` does not include the `:eol-style` parameter, it then also analyses the start of the file for byte patterns indicating the end-of-line style, and uses a default end-of-line style if no such pattern is found.

The file in this example was written by a Windows program which writes the Byte Order Mark at the start of the file, indicating that it is Unicode (UCS-2) encoded. The routine in step 1 above detects this:

```
(set-default-character-element-type 'simple-char)
=>
SIMPLE-CHAR

(with-open-file (ss "C:/temp/unicode-notepad.txt")
  (stream-external-format ss))
=>
(:UNICODE :LITTLE-ENDIAN T :EOL-STYLE :CRLF)
```

The behavior of `guess-external-format` is configurable via the variables `*file-encoding-detection-algorithm*` and `*file-eol-style-detection-algorithm*`. See the manual pages for details.

22.6.3.1 Example of using UTF-8 by default

To change the default for all file access via `open`, `compile-file` and so on, you can modify the value of `*file-encoding-detection-algorithm*`.

For example given the following definition:

```
(defun utf-8-file-encoding (pathname ef-spec buffer length)
  (declare (ignore pathname buffer length))
  (system:merge-ef-specs ef-spec :utf-8))
```

then this makes it use UTF-8 as a fallback:

```
(setq system:*file-encoding-detection-algorithm*
      (substitute 'utf-8-file-encoding
                  'system:locale-file-encoding
                  system:*file-encoding-detection-algorithm*))
```

and this forces it to always use UTF-8:

```
(setq system:*file-encoding-detection-algorithm*
      '(utf-8-file-encoding))
```

22.6.4 External formats and stream-element-type

The `:element-type` argument in `open` and `with-open-file` defaults to the value of `*default-character-element-type*`.

If *element-type* is not `:default`, checks are made to ensure that the resulting stream's `stream-element-type` is compatible with its external format:

1. If *direction* is `:input` or `:io`, the *element-type* argument must be a supertype of the type of characters produced by the external format.
2. If *direction* is `:output` or `:io`, the *element-type* argument must be a subtype of the type of characters accepted by the external format

If the *element-type* argument does not satisfy these requirements, an error is signalled.

If *element-type* is `:default` the system chooses the `stream-element-type` on the basis of the external format.

22.6.5 External formats and the LispWorks Editor

The LispWorks Editor uses `open` with `:element-type :default` to read and write files. On reading a file, the external format is remembered and used when saving the file. On writing a Unicode (UCS-2) file, the Byte Order Mark is written.

It is possible to insert characters in the Editor (for example by pasting clipboard text) which are not supported by the chosen external format. This will lead to errors on attempt to save the buffer. You can handle this by setting the external format appropriately.

See the *LispWorks Editor User Guide* for more details.

22.6.6 Byte Order Mark

The Unicode Byte Order Mark (BOM) is treated as whitespace in the default readtable. This allows the Lisp reader to read a Unicode (UCS-2 encoded, *external-format :unicode*) file regardless of whether the BOM is present.

Some editors including Microsoft Notepad and the LispWorks editor write the BOM when writing a file with Unicode (UCS-2) encoding.

22.7 External Formats and the Foreign Language Interface

External formats can be used to pass and receive string data via the FLI. See the section on string types in the *LispWorks Foreign Language Interface User Guide and Reference Manual*.

22.8 Unicode character and string functions

This section lists functions which compare characters and strings similarly to `cl:char-equal`, `cl:string-greaterp` and so on, but which use Unicode's simple case folding rules.

There are also predicates for properties of characters in Unicode's "general category", corresponding to `cl:alpha-char-p`, `cl:both-case-p` and so on.

22.8.1 Unicode case insensitive character comparison

The functions `unicode-char-equal`, `unicode-char-not-equal`, `unicode-char-lessp`, `unicode-char-not-lessp`, `unicode-char-greaterp` and `unicode-char-not-greaterp` compare characters similarly to `cl:char-equal` etc, but using Unicode's simple case folding rules.

22.8.2 Unicode case insensitive string comparison

The functions `unicode-string-equal`, `unicode-string-not-equal`, `unicode-string-lessp`, `unicode-string-not-lessp`, `unicode-string-greaterp` and `unicode-string-not-greaterp` compare strings similarly to `cl:string-equal` etc, but using Unicode's simple case folding rules.

22.8.3 Unicode character predicates

The predicates `unicode-alphanumeric-p`, `unicode-alpha-char-p`, `unicode-lower-case-p`, `unicode-upper-case-p` and `unicode-both-case-p` test for properties of a character in Unicode's "general category".

23

LispWorks' Operating Environment

This chapter describes the interfaces which provide information about the environment in which LispWorks is running. This includes the operating system, the file system, the physical location of the LispWorks executable, and the arguments it was passed on startup.

23.1 The Operating System

The Common Lisp function `software-type` returns a generic name for the Operating System. The Common Lisp function `software-version` returns information about the version of the Operating System.

In particular `software-type` can be used to distinguish between systems based on Windows 95 and those based on Windows NT. `software-version` allows you to identify variants such as Windows XP, Windows Vista, Windows 7 and so on. See the manual pages for details.

23.2 Site Name

The Common Lisp functions `short-site-name` and `long-site-name` can be configured using `setf`:

```
(setf (long-site-name) "LispWorks Ltd"  
      (short-site-name) "LW")
```

23.3 The Lisp Image

The function `lisp-image-name` returns the namestring of the full path of the LispWorks executable or dynamic library (DLL). For example, the directory of the image can be found using:

```
(pathname-location (lisp-image-name))
```

To create a new executable or DLL, typically after loading patches, modules and application code, use `save-image` or `deliver`.

Note: Microsoft Windows supports Long and Short forms of paths. You may need to convert a namestring using `long-namestring` or `short-namestring`.

23.4 The Command Line

The command line used to run LispWorks can be found using the variable `*line-arguments-list*`. The value is a list of strings containing the executable name followed by any other command line arguments, in the order they were passed.

For example, if your application needs to behave differently when passed an argument `-foo`, use the following test:

```
(member "-foo" sys:*line-arguments-list* :test 'string=)
```

23.4.1 Command Line Arguments

The following command line options are supported by the system.

-build *build-script*

Typically this is used for the purpose of building another image.

build-script can name a file to be loaded on startup. This file will be the build script which loads your code and calls `save-image` or `deliver`. LispWorks quits after loading the file. If an error is signalled while loading the file, a backtrace is displayed and LispWorks quits.

build-script can also be `-`, a single minus sign. Passing `-build -` causes LispWorks to read and execute a build script from stdin. This is useful if you want to embed a build script within a shell script that runs LispWorks, for example:

```
lispworks-6-1-0-x86-linux -build - <<END
(write-line "This is the build script.")
END
```

Note that this technique using `<<END` does not work on Microsoft Windows.

An image run with `-build` runs itself, and not the default saved session if you created one. See “Saved sessions” on page 137 for information on saved sessions.

`-build` calls `load-all-patches` automatically. There is no harm if your build script also calls `load-all-patches`.

-environment Start the LispWorks IDE development environment automatically, even in an image saved with (`save-image ... :environment nil`)

-eval form Evaluates the Lisp form *form* before loading initialization files.

-env A synonym for `-environment`.

-display display

Sets the X display to use when starting a LispWorks GUI on X Windows.

-IIOPhost host

Controls the host name in placed in IORs. See *Developing Component Software with CORBA* for details.

-IIOPnumeric

IORs contain a host name which is the numeric IP address obtained by reverse lookup of the machine name. See *Developing Component Software with CORBA* for details.

-init *init-file* *init-file* names a file to be loaded on startup after *siteinit-file*. The file is user's own LispWorks initialization file, containing code that by default is loaded when LispWorks is started. It is useful for loading initializations that should not be done for all users.

Initially the default is to load the file "`~/.lispworks`" where `~` expands to the user's home directory as described in "Configuration and initialization files" on page 134.

Your default initialization file can be set in the LispWorks IDE. See "Setting Preferences" in the *LispWorks IDE User Guide* for details.

If *init-file* is not found, an error is signalled. To suppress loading of a user initialization file, pass `-init -`.

-load *file* Loads the file *file* before loading initialization files.

-lw-no-redirection

Makes the supplied image run itself, and not the default saved session if you created one. See "Saved sessions" on page 137 for information on saved sessions.

-multiprocessing

Initializes multiprocessing on startup. See Chapter 15, "Multiprocessing".

-no-restart-function

Suppresses the execution of a restart function on startup. Restart functions can be supplied when saving an image to automatically invoke application code. This argument suppresses that behavior. See `save-image`, page 638.

-ORBport *orbport*

orbport specifies a port number for the LispWorks ORB. The special value 0 allows the system to pick a port.

--relocate-image *BaseAddress*

Causes the image to relocate at *BaseAddress* on supported platforms, as described in “Startup relocation” on page 314. This can be useful on a system where libraries are mapped in address space that LispWorks would otherwise use as it grows. If the image is saved, then on restart without **--relocate-image**, it will locate itself automatically at *BaseAddress*.

Compatibility Note: In LispWorks 5.0 and earlier versions, to be effective, **--relocate-image** must be the first argument on the LispWorks command line. This restriction does not apply in LispWorks 6.1.

--reserve-size *ReserveSize*

Specifies the reserve size on supported platforms, as described in “Startup relocation” on page 314. New in LispWorks 5.1.

-siteinit *siteinit-file*

siteinit-file names a file to be loaded on startup. The file is the LispWorks site initialization file, containing code that by default is loaded when LispWorks is started by any user in that installation. The default is to load the file that is the result of evaluating

`(sys:lispworks-file "config/siteinit.lisp")`.

If *siteinit-file* is not found, an error is signalled. To suppress loading of a site initialization file, pass **-siteinit -**.

23.5 Address Space and Image Size

There are two factors that affect the maximum size of the Lisp image: the size of real memory, and the layout of memory. On most platforms you can relocate LispWorks to avoid clashes with other software as described in “Startup relocation” on page 314.

23.5.1 Size of real memory

If LispWorks becomes significantly larger than the size of the real memory, then paging will be the main activity and LispWorks will not function effectively.

23.5.2 Layout of memory

This is Operating System-dependent:

On Solaris, 32-bit LispWorks is mapped at `#x10000000`. In principle it can grow to almost `#x80000000` (the libraries are at higher addresses).

On HP-UX, 32-bit LispWorks is mapped at `#x50000000`, because it cannot use the first quadrant. The libraries are also mapped at the same quadrant, at around `#x7a000000`, so the total size can be a little more than 0.5GB.

For the other platforms and for 64-bit LispWorks, see the discussion in “Startup relocation” on page 314.

23.5.3 Reporting current allocation

The simplest way to see the current Lisp allocation is to call `(room t)`.

To obtain values representing the current total allocation, call `room-values`.

23.6 Startup relocation

On startup, LispWorks normally maps its heap at the address where it was mapped when the image was saved. It maps more memory close to this when needed. This may cause memory clashes with other software, but such clashes may be avoided by relocating LispWorks.

32-bit LispWorks is relocatable on Microsoft Windows, Intel Macintosh, Linux, x86/x64 Solaris and FreeBSD. The 32-bit LispWorks implementations on non-x86 platforms are not relocatable. 64-bit LispWorks is relocatable on all supported platforms. The discussion in this section is applicable to all relocatable implementations.

On Microsoft Windows and Macintosh, LispWorks detects memory clashes and avoids them automatically. On these platforms there is no need to explic-

itly relocate LispWorks. The other relocatable implementations - LispWorks (32-bit) for Linux, LispWorks (64-bit) for Linux, LispWorks (32-bit) for FreeBSD, LispWorks (64-bit) for FreeBSD, LispWorks (32-bit) for x86/x64 Solaris, LispWorks (64-bit) for x86/x64 Solaris, and LispWorks (64-bit) for SPARC/Solaris - cannot safely detect memory clashes. Relocation may therefore be useful in these implementations.

23.6.1 How to relocate LispWorks

Relocate LispWorks by passing two parameters: the base address and the reserve amount. Both are optional. The interpretation of these parameters is very different between 64-bit LispWorks and 32-bit LispWorks.

To relocate a LispWorks executable on non-Windows platforms, pass one or both of these command line arguments:

--relocate-image *BaseAddress*

The base address, interpreted as a hexadecimal number
by calling `strtol(BaseAddress, NULL, 16)`)

--reserve-size *ReserveSize*

The reserve size, interpreted as a hexadecimal number
by calling `strtol(ReserveSize, NULL, 16)`)

There is currently no way to control the relocation of a LispWorks for Windows executable.

On all relocatable platforms, a LispWorks dynamic library or Windows DLL can be relocated by calling `InitLispWorks` with second and/or third argument non-zero.

On non-Windows platforms, you can add the appropriate call to `InitLispWorks` in wrappers written in C and added to the dynamic library by passing `dll-added-files` to `save-image` or `deliver`. There is no such option in LispWorks for Windows.

The startup relocation takes some time, normally less than 0.1 seconds on a modern machine. If the relocation address is fixed and known, this startup overhead can be eliminated by relocating the image before calling `save-image` or `deliver`.

23.6.2 Startup relocation of 32-bit LispWorks

32-bit LispWorks on x86 platforms maps its heap in one continuous block, and then grows upwards from the top. When it reaches a region that it cannot use, it can skip it. On Windows and Macintosh this skipping is safe, because LispWorks can safely detect regions of memory that it cannot use. On other x86 platforms, both the initial mapping and the further growing cannot safely detect when they overwrite some other code.

BaseAddress (passed on command line with `--relocate-image` or as the second argument to `InitLispWorks`) tells LispWorks where to map the heap. On Windows and Macintosh, if the address is already used the heap will be mapped elsewhere. On other platforms, the mapping always works, and may destroy what is already mapped at that address.

ReserveSize (passed on command line with `--reserve-size` or as the third argument to `InitLispWorks`) tells LispWorks how much additional memory to reserve. Reservation is properly supported on Windows and Macintosh, though the actual reserved size can be smaller if it fails to reserve as much as was requested. On platforms that do not support reservation (that is, not Windows or Macintosh), the reservation is done by using `mmap` with protection `PROT_NONE`.

23.6.2.1 Linux

On Linux, the default initial heap is mapped at address `#x2000000` (0.5GB). LispWorks then tries to locate the location of dynamic libraries, and marks a region around these libraries that should not be used (by default 64MB from the bottom). In most cases this suffices to avoid clashes.

Problems can arise if the memory at `#x20000000` or above is already used by another part of the software. If that memory gets used before LispWorks is mapped, LispWorks must be relocated elsewhere, typically to a higher address.

If the memory above LispWorks gets used by other parts of the software after LispWorks was mapped, it may be possible to avoid the problem by reserving some memory above LispWorks by supplying *ReserveSize*.

The location of dynamic libraries differs between Linux configurations, and that needs to be taken into account. For most cases, including the cases where

the libraries are mapped at `#x40000000` or somewhere above `#x28000000`, the mechanism for detecting libraries works and no action is required.

In principle LispWorks (32-bit) for Linux can grow up to some distance below `#xBF000000` (almost 2.5GB), though this depends on the OS kernel allowing this size.

Note: In LispWorks 5.0 and previous, we told some customers to relocate above the libraries, for example at `#x50000000` or `#x48000000`, but this should not be needed in LispWorks 6.1.

23.6.2.2 FreeBSD

By default, LispWorks is mapped at `#x30000000`.

Problems may arise if something uses memory above `#x30000000`. If this memory is used before LispWorks is mapped, LispWorks must be relocated elsewhere, typically to a higher address.

If the memory above LispWorks gets used by other parts of the software after LispWorks was mapped, it may be possible to avoid the problem by reserving some memory above LispWorks by using *ReserveSize*.

Normally the dynamic libraries are mapped at `#x28000000`, and therefore LispWorks can grow without a problem.

In principle LispWorks can grow up to some distance below `#xC0000000` (almost 2.25GB), though this depends on the OS kernel allowing this size and how many threads you have running.

23.6.2.3 x86/x64 Solaris

The default initial heap is mapped at address `#x10000000` (0.25GB).

LispWorks then tries to locate the location of dynamic libraries, and marks a region around these libraries that should not be used (by default 64MB from the bottom). In most cases this suffices to avoid clashes.

Problems can arise if the memory at `#x10000000` or above is already used by another part of the software. If that memory gets used before LispWorks is mapped, LispWorks must be relocated elsewhere, typically to a higher address.

If the memory above LispWorks gets used by other parts of the software after LispWorks was mapped, it may be possible to avoid the problem by reserving some memory above LispWorks by supplying *ReserveSize*.

23.6.2.4 Windows and Macintosh

LispWorks (32-bit) for Windows and LispWorks (32-bit) for Macintosh both map by default at #x20000000. Since these platforms support reservation, normally you will not need to do anything special about this.

Problems may however arise if LispWorks operates in conjunction with non-relocatable software which insists on using addresses at #x20000000 or some distance above, in which case you will need to relocate LispWorks.

LispWorks (32-bit) for Windows can in principle grow up to some distance below #x80000000 (almost 1.5GB) but there is always the possibility that some DLL will be mapped in this region. On startup, it reserves 0.5GB above its location, so that much is guaranteed.

LispWorks (32-bit) for Macintosh can grow to around 2.7GB. You can relocate it only on the Intel architecture.

23.6.3 Startup relocation of 64-bit LispWorks

The size of address space that 64-bit LispWorks can use is limited by the size of internal tables to a "span" of 2^{44} (16TB). The span always starts at 0.

Inside this span LispWorks can use any address. However, to avoid clashes with other software, it uses memory only in some defined range.

Startup relocation means changing this range. *BaseAddress* (passed on command line with `--relocate-image` or as the second argument to `InitLispWorks`, rounded up to 2^{28}) is the start of the range. *ReserveSize* (passed on command line with `--reserve-size` or as the third argument to `InitLispWorks`) is the size of the range. The default of the size of the range is 2^{40} .

If the entire heap is within the new range, nothing else is done. If some part of the heap is outside the new range, the heap is relocated.

The range in each 64-bit LispWorks implementation starts at #x4000000000 (256GB).

23.6.3.1 Linux

On old Linux systems LispWorks (64-bit) for Linux has range 192GB, ending at `#x7000000000`, because old Linux systems cannot map above `#x8000000000` and put the dynamic libraries just below that limit (at least in some configurations). Since LispWorks uses the address space sparsely, it will run out of memory with less virtual memory, probably around 150GB to 160GB. If more memory is required, the range can be extended downwards, and possibly some distance upwards too. If other software uses memory in the range from `#x4000000000` to `#x7000000000`, LispWorks should be relocated (potentially just by decreasing the range) to avoid memory clashes.

Modern Linux systems have a much larger address space and the default size of the LispWorks range is `#x4000000000` (4TB).

23.6.3.2 SPARC Solaris

In LispWorks (64-bit) for SPARC Solaris the default range is 768GB, ending at `#x10000000000`. If other software uses memory in this range, the range for LispWorks should be decreased to avoid memory clashes.

23.6.3.3 Windows and Macintosh

In LispWorks (64-bit) for Windows and LispWorks (64-bit) for Macintosh the size of the range is `#x3c000000000` (3.75TB). Since these platforms properly support reservation, there should not be any reason to change the range. The only time when this is needed is when other software insists on using some address in this range and does not relocate automatically.

23.7 Calling external programs

You can call an external program using `call-system`, `call-system-showing-output` and `open-pipe`.

You can call C programs using the FLI. See the *LispWorks Foreign Language Interface User Guide and Reference Manual*.

On Microsoft Windows a COM/Automation interface is provided. See the *LispWorks COM/Automation User Guide and Reference Manual*. There is also a DDE interface - see Chapter 18, “Dynamic Data Exchange”.

On Mac OS X an Objective-C API is provided. See the *LispWorks Objective-C and Cocoa Interface User Guide and Reference Manual*.

23.8 Snapshot debugging of startup errors

When an error occurs during initialization (for example, because of code in an initialization file) and the image is configured to start the LispWorks IDE, by default it catches the error, starts the IDE and displays the error in a snapshot debugger.

You should note that because this is a snapshot, you cannot actually continue or abort or return from a frame. The snapshot debugger is simply a tool to help debugging the error.

The behavior is controlled by the variable `*debug-initialization-errors-in-snap-shot*`.

23.9 System message log

The system message log is used by the system to produce messages that indicate that something is not as expected, where this is not an error. You can manipulate the log with `set-system-message-log`.

23.10 Exit status

You can return a process exit status to the Operating System when LispWorks or a delivered LispWorks application quits.

Do this by passing a *status* value to the function `quit`. For example:

```
(quit :status 42)
```

23.11 Creating a new executable with code preloaded

There are two ways to create a new executable with your code preloaded.

- To write a copy of the currently running image to disk, use `save-image`, page 638. The saved image requires a development license key to run.

- To create a runtime image, removing unused code to make the image smaller, call `deliver`. For more details see the *LispWorks Delivery User Guide*.

For example of how to use `save-image`, see the section "Saving and testing the configured image" in the *LispWorks Release Notes and Installation Guide*.

See Section 23.12 for information about universal binaries on Mac OS X.

23.12 Universal binaries on Mac OS X

The supplied LispWorks for Macintosh images are universal binaries, which run the correct native architecture on PowerPC and Intel-based Macintosh computers by default.

A running Lisp image only supports one architecture, chosen when the image was started. On a PowerPC based Macintosh, this is always the PowerPC architecture. On an Intel-based Macintosh, a 32-bit LispWorks image can be either the native Intel architecture or the PowerPC architecture (using Rosetta), but a 64-bit LispWorks image can only be the Intel architecture (because there is no 64-bit Rosetta).

Functions such as `save-image` and `deliver` mentioned in Section 23.11 create an image containing only the running architecture and functions that operate on fasl files such as `compile-file` and `load` only support the running architecture.

23.12.1 Building 32-bit universal binary applications

To build a universal binary application from 32-bit LispWorks for Macintosh, you will need to install 32-bit LispWorks on an Intel-based Macintosh computer.

Building a new universal binary requires three steps:

1. Build the application for PowerPC.
This can be done on your Intel machine using Rosetta
2. Build the application for Intel.
3. Combine the two applications to make a universal binary.

These steps can be automated on a single Intel-based Macintosh by creating a script that compiles and loads the application and then saves the image. Loading this by running LispWorks with the `-build` command line argument would save an image containing a single architecture, but you can use the same script to save a universal binary by calling `save-universal-from-script`, page 648.

Note: You may install LispWorks on multiple machines for use at the same time only if you own multiple LispWorks licenses.

23.12.2 Building 64-bit universal binary applications

To create a universal binary application from LispWorks (64-bit) for Macintosh, you will need to install 64-bit LispWorks on both a PowerPC Macintosh and an Intel-based Macintosh computer, and deliver on both machines. Contact Lisp Support if you need advice on creating a 64-bit universal binary after that.

23.13 User Preferences

LispWorks provides an API for setting and querying persistant per-user settings in a platform-dependent registry.

23.13.1 Location of persistant settings

On Microsoft Windows the preferences are stored in the `HKEY_CURRENT_USER` branch of the Windows registry. (LispWorks also offers a general Windows registry API, described in “Accessing the Windows registry” on page 325.)

On non-Windows the preferences are stored in subdirectories of the user’s home directory.

To implement preferences for your LispWorks application, you will need to define a registry path using (`setf product-registry-path`) and read it using `product-registry-path`.

23.13.2 Accessing persistant settings

Get and set preferences under the product path at runtime with `user-preference` and `(setf user-preference)`.

23.13.3 Example using user preferences

Define a registry path:

```
(setf (sys:product-registry-path :deep-thought)
      '("Software" "My Company" "Deep Thought"))
```

Store a preference for the current user:

```
(setf (user-preference "Answers"
                        "Ultimate Question"
                        :product :deep-thought)
      42)
```

Retrieve a preference for the current user, potentially in a subsequent session:

```
(user-preference "Answers" "Ultimate Question"
                :product :deep-thought)
```

23.14 Special locations in the file system

This section describes interfaces allowing you to identify and access various special locations in the file system.

23.14.1 The home directory

This section describes the implementation of the Common Lisp function `user-homedir-pathname`.

On Unix-based systems, the home directory is looked up using the C function `getpwuid`.

On Microsoft Windows systems, `user-homedir-pathname` uses the environment to construct its result. It uses the values of the environment variables HOMEDRIVE and HOMEPATH, if both are defined. If at least one of environment variables HOMEDRIVE and HOMEPATH is not defined, then a pathname `#P"C:/users/login-name"` is returned. These environment variables

should be correctly set before LispWorks starts. However it is possible to change the values in Lisp using

```
(setf environment-variable)
```

23.14.2 Special Folders

On Microsoft Windows and Mac OS X there are various special folders used for application data and user data. Here are some examples of the folder for application data which is shared between all users.

Windows 7 and Windows Vista:

```
C:\ProgramData
```

Windows XP:

```
C:\Documents and Settings\All Users.WINDOWS\Application Data
```

Mac OS X:

```
/Library/Application Support
```

The locations and folder names can differ between versions of the operating system, therefore it is useful to have a system-independent way to get the path at runtime. The function `get-folder-path` can be used to retrieve the path to special folders. Directory pathnames corresponding to each of the examples above can be obtained by calling:

```
(sys:get-folder-path :common-appdata)
```

Here is another example of differences between operating systems. On Windows 7 and Windows Vista:

```
(sys:get-folder-path :my-documents)
=>
#P"C:/Users/dubya/Documents/"
```

On Windows 98 SE:

```
(sys:get-folder-path :my-documents)
=>
#P"C:/My Documents/"
```

On Mac OS X:

```
(sys:get-folder-path :my-documents)
=>
#P"/u/ldisk/dubya/Documents/"
```

See `get-folder-path` for more details.

On Windows NT-based systems there is a profile folder for each user. You can find the profile path for the current user with the function `get-user-profile-directory`.

23.14.3 Temp files

A "temp file" is a file in the "temp directory" which is guaranteed to be new. Its name contains a random element.

Create a temp file by calling either of the functions `open-temp-file` and `create-temp-file`. For example:

On Microsoft Windows:

```
(create-temp-file :prefix "LW")
=>
#P"C:/DOCUME~1/dubya/LOCALS~1/Temp/LW383vwVfZN.tmp"
```

On Linux:

```
(create-temp-file :prefix "LW")
=>
#P"/tmp/LW1adokNa.tmp"
```

The function `set-temp-directory` allows you to set the "temp directory", that is the default directory used for temp files.

23.15 Accessing the Windows registry

There is an API for accessing the registry on Microsoft Windows. It is available only in LispWorks for Windows. All of its symbols are in the `win32` package.

Create and delete keys with the functions `create-registry-key` and `delete-registry-key`. Open a key for reading and/or writing with `open-registry-key` and close it with `close-registry-key`, or wrap your registry operation inside the macro `with-registry-key`.

Query the registry with `registry-key-exists-p`, `enum-registry-value`, `collect-registry-values`, `collect-registry-subkeys`, `query-registry-key-info`, `query-registry-value`, and `registry-value`. Write to the registry with `set-registry-value` OR `(setf registry-value)`.

For example, this function returns the name, progid and filename for each of the installed ActiveX controls:

```
(defun collect-control-names (&key insertable
                                         (max-name-size 256)
                                         (max-names most-positive-fixnum))
  (win32:collect-registry-subkeys
    "CLSID"
    :root :root
    :max-name-size max-name-size
    :max-names max-names
    :value-function
    #'(lambda (hKeyClsid ClassidName)
        (win32:with-registry-key
          (hkeyX ClassidName :root hKeyClsid :errorp nil)
          (when (and
                  (win32:registry-key-exists-p "Control"
                                                :root hkeyX)
                  (if insertable
                      (win32:registry-key-exists-p "Insertable"
                                                    :root hkeyX)
                      t))
            (when-let
              (progid (win32:query-registry-value "ProgID" nil
                                                    :root hkeyX
                                                    :errorp nil))
              (values
                (list
                  (win32:query-registry-value nil nil
                                                :root hkeyX)
                  progid
                  (win32:query-registry-value "InprocServer32" nil
                                                :root hkeyX
                                                :errorp nil)))
              t)))))))
```

23.16 Pathname comparison on Mac OS X

Comparing pathnames using `equal` and `equalp` is case-sensitive on the Macintosh. This can lead to occasional unexpected mismatch of pathnames,

because the HFS+ filesystem is usually case-insensitive (some Macintosh file-systems are case-sensitive).

24

64-bit LispWorks

This chapter summarises the technical differences between 64-bit LispWorks and 32-bit LispWorks. Both are ANSI Common Lisp implementations and support the language same extensions and libraries so in many ways they behave the same. However the programmer should be aware of the differences mentioned here.

24.1 Introduction

64-bit LispWorks has a larger address space, subject to physical memory. The maximum heap sizes are shown in Table 24.1.

You can make larger arrays and the `fixnum` type is much larger than in 32-bit LispWorks. The values of various Common Lisp architectural constants reflect this, as shown in Table 24.2.

Other differences in 64-bit LispWorks are noted in the remaining sections of this chapter.

24.2 Heap size

In principle 64-bit LispWorks can grow to almost 16TB but it is intentionally limited to a defined range in order to avoid clashes with other software as shown in Table 24.1.

Table 24.1 Default range for 64-bit LispWorks heap

Platform	Default range	Notes
Intel-based Macintosh	#x4000000000 to #x4000000000 (3.75TB)	
PowerPC Macintosh	#x4000000000 to #x4000000000 (3.75TB)	
old Linux	#x4000000000 to #x7000000000 (192GB)	Effective limit around 160GB.
modern Linux	#x4000000000 to #x4400000000 (4TB)	
Windows	#x4000000000 to #x4000000000 (3.75TB)	
Solaris	#x4000000000 to #x10000000000 (768GB)	

In contrast, 32-bit LispWorks has a maximum heap size of 1.5-3.0GB depending on platform.

Normally 64-bit LispWorks for Linux automatically adjusts its default heap size on startup according to whether it runs on "old Linux" or "new Linux". On old systems, LispWorks sets the end of its range to `x7000000000`. On new systems, it sets the end to `#x4400000000`, thus giving a range of 4TB. However, if the size is given explicitly by command line argument `--reserve-size` or `InitLispWorks` in a dynamic library, then this overrides the automatic adjustment.

LispWorks is relocatable on all supported platforms as described in “Startup relocation of 32-bit LispWorks” on page 316 and “Startup relocation of 64-bit LispWorks” on page 318.

24.3 Architectural constants

Common Lisp constants have the values shown in Table 24.2

Table 24.2 Architectural constants

Constant	32-bit LispWorks	64-bit LispWorks
<code>most-positive-fixnum</code>	$2^{29} - 1$	$2^{60} - 1$
<code>array-dimension-limit</code>	67108337 (almost 2^{26})	$2^{29} - 1$
<code>array-total-size-limit</code>	2^{26}	$2^{29} - 1$

Note: In 32-bit LispWorks 5.0, `array-total-size-limit` is $2^{29} - 1$, which is wrong.

24.4 Speed

64-bit LispWorks is generally faster than 32-bit LispWorks.

We would be interested to see comparative performance data from your application if it runs on both 32-bit and 64-bit LispWorks.

24.5 Memory Management

Memory layout and the garbage collector (GC) differs significantly between the two implementations.

For the details see “Memory Management in 32-bit LispWorks” on page 109 and “Memory Management in 64-bit LispWorks” on page 117.

24.6 Float types

In 64-bit LispWorks `single-floats` are immediate objects, and `short-float` is the same type as `single-float`.

In 32-bit LispWorks `single-floats` are boxed objects, and `short-float` is disjoint from other float types.

24.7 External libraries

Third party libraries loaded into 64-bit *LispWorks* must be 64-bit. Availability of a suitable library is therefore a possible issue when porting your *LispWorks* application to 64-bit.

Third party libraries loaded into 32-bit *LispWorks* must be 32-bit.

25

The CLOS Package

This chapter describes the LispWorks extensions to CLOS, the Common Lisp Object System.

The LispWorks Meta Object Protocol mostly conforms to chapters 5 & 6 of AMOP. Manual pages for symbols with different functionality from AMOP are in this chapter, and the differences are discussed in Chapter 14, “The Metaobject Protocol”.

		<i>Function</i>
Summary		Breaks to the debugger when a new instance of a class is accessed. Note that this function is deprecated.
Package		<code>clos</code>
Signature		<code>break-new-instances-on-access <i>class-designator</i> &key <i>read</i> <i>write</i> <i>slot-names</i> <i>when</i> <i>process</i> <i>trace-output</i> <i>entrycond</i> <i>eval-before</i> <i>before</i> <i>backtrace</i> => <i>t</i></code>
Arguments		<i>class-designator</i> The class to trap.
Values		Returns <i>t</i> .

Description	Causes a break when new instances of the class given by <i>class-designator</i> are accessed, according to the keyword arguments.
	The keyword arguments control which type of access cause a break and are interpreted as described for <code>trace-on-access</code> .
	Note: this function is deprecated. You should now call <code>trace-new-instances-on-access</code> with <code>:break t</code> instead.
See also	<code>trace-new-instances-on-access</code>

	<i>Function</i>
break-on-access	
Summary	Breaks to the debugger when an instance of a class is accessed. Note that this function is deprecated.
Package	<code>clos</code>
Signature	<code>break-on-access instance &key read write slot-names when process trace-output entrycond eval-before before backtrace => t</code>
Arguments	<code>instance</code> A CLOS instance.
Values	Returns <code>t</code> .
Description	A useful debugging function which causes access to <i>instance</i> to break to the debugger. Accesses include calls to <code>slot-value</code> and also accessor functions defined by the class of <i>instance</i> . Other instances of the same class are unaffected. The keyword arguments control which type of access cause a break and are interpreted as described for <code>trace-on-access</code> . You can remove the break by calling <code>unbreak-on-access</code> . A common use of this function is to find where a slot is being changed in a complex program.

Note: this function is deprecated. You should now call `trace-on-access` with `:break t` instead.

See also [trace-on-access](#)

class-extra-initargs

Generic Function

Summary	Extends the valid initialization arguments of a class.	
Package	clos	
Signature	<code>class-extra-initargs prototype => initargs</code>	
Arguments	<code>prototype</code>	A class prototype.
Values	<code>initargs</code>	A list of additional initialization arguments.
Description	<p>The generic function <code>class-extra-initargs</code> lets you extend the set of valid initialization arguments for a class and its subclasses. <code>initargs</code> should be a list of symbols. Each symbol becomes a valid initarg for the class. By default in a non-delivered LispWorks image, <code>make-instance</code> and other CLOS initializations (see <code>set-clos-initarg-checking</code>) check that initargs passed to them are valid.</p> <p>The extra initargs are used for <code>make-instance</code>, <code>reinitialize-instance</code>, <code>update-instance-for-redefined-class</code> and <code>update-instance-for-different-class</code>.</p>	
Notes	<p><code>class-extra-initargs</code> is useful only in complex cases. In most cases other ways of extending the set of valid initargs are simpler and clearer, such as the <code>:extra-initargs</code> class option, described in <code>defclass</code>.</p>	
Example	<p>In this session an illegal initarg <code>:my-keyword</code> is passed, causing <code>make-instance</code> to signal an error.</p>	

Then `:my-keyword` is added as an extra initarg, after which `make-instance` accepts it.

```
CL-USER 38 > (defclass my-class () ((a :initform nil)))
#<STANDARD-CLASS MY-CLASS 113AAA2F>

CL-USER 39 > (make-instance 'my-class :my-keyword 8)

Error: MAKE-INSTANCE is called with unknown keyword
:MY-KEYWORD among the arguments (MY-CLASS :MY-KEYWORD
8) {no keywords allowed}
  1 (continue) Ignore the keyword :MY-KEYWORD
  2 (abort) Return to level 0.
  3 Return to top loop level 0.

Type :b for backtrace, :c <option number> to proceed,
or :? for other options

CL-USER 40 : 1 > :a

CL-USER 41 > (defmethod clos:class-extra-initargs
                ((x my-class))
                '(:my-keyword))
#<STANDARD-METHOD CLOS:CLASS-EXTRA-INITARGS (MY-CLASS)
1137C763>

CL-USER 42 > (make-instance 'my-class :my-keyword 8)
#<MY-CLASS 11368963>
```

`defclass`
`make-instance`
`set-clos-initarg-checking`

compute-class-potential-initargs

Generic Function

Summary Computes the valid initargs of a class.

Package `clos`

Signature `compute-class-potential-initargs class => initargs`

Arguments	<i>class</i>	A class.
Values	<i>initargs</i>	A list of symbols, or <code>t</code> .
Description	<p>The generic function <code>compute-class-potential-initargs</code> is called to compute the initialization arguments of a class. This set of valid initargs is used by <code>make-instance</code> when its arguments are checked.</p> <p><i>class</i> is the class passed to <code>make-instance</code>. That is, <code>compute-class-potential-initargs</code> specializes on the metaclass.</p> <p><i>initargs</i> is either a list of valid initargs, or <code>t</code> meaning that any initialization argument is allowed.</p> <p>There is a supplied method on <code>t</code>, which returns <code>nil</code>.</p> <p>The other supplied method is on <code>standard-class</code>. This consults the Relevant Methods, which are the applicable methods of <code>make-instance</code>, <code>allocate-instance</code>, <code>initialize-instance</code> and <code>shared-initialize</code>. If any of the Relevant Methods have a lambda list containing <code>&allow-other-keys</code> then <i>initargs</i> is <code>t</code>. Otherwise <i>initargs</i> is a list containing:</p> <ul style="list-style-type: none"> • all the <code>&key</code> arguments from Relevant Method lambda lists, and • the initargs of the slots of <i>class</i> and its superclasses, and • any extra initargs specified via the class option <code>:extra-initargs</code> (see <code>defclass</code> for details of this), and • any extra initargs returned by <code>class-extra-initargs</code>. <p>The list <i>initargs</i> contains no duplicates, and the result of <code>compute-class-potential-initargs</code> is cached so that it is not recomputed unless one of the Relevant Methods, the class or its class precedence list is altered.</p>	

See also `class-extra-initargs`
`make-instance`
`set-clos-initarg-checking`

compute-discriminating-function *Generic Function*

Summary Returns the discriminating function.

Package `clos`

Signature `compute-discriminating-function gf => result`

Arguments `gf` A generic function.

Values `result` A function.

Description The generic function `compute-discriminating-function` returns the discriminator as specified in AMOP.

However, there are two discrepancies with the AMOP behavior:

- The discriminating function does not `compute-applicable-methods-using-classes`, since this is not implemented.
- `add-method` does not call `compute-discriminating-function`. Instead, it is called when the generic function is called. This is more efficient than calling `compute-discriminating-function` each time `add-method` is called.

funcallable-standard-object *Class*

Package `clos`

Superclasses `function`
`standard-object`

Subclasses	<code>generic-function</code>
Description	<p>The metaclass <code>funcallable-standard-object</code> provides the default <code>:direct-superclasses</code> for instances of <code>funcallable-standard-class</code> and its subclasses.</p> <p><code>funcallable-standard-object</code> is implemented as described in AMOP except for a different order in the class precedence list.</p>
In AMOP the class precedence list is	
<pre>(funcallable-standard-object standard-object function t)</pre>	
whereas in LispWorks the class precedence list is	
<pre>(funcallable-standard-object function standard-object t)</pre>	
LispWorks is like this to be compliant with the rules in the ANSI Common Lisp Standard.	
The AMOP class precedence list implies a class precedence for <code>generic-function</code> which violates the last sentence in ANSI Common Lisp 4.2.2 Type Relationships. See www.lisp-works.com/reference/HyperSpec/Body/04_bb.htm .	

process-a-class-option *Generic Function*

Summary	Describes how the value of a class option is parsed.		
Package	<code>clos</code>		
Signature	<code>process-a-class-option metaclass option value => initargs</code>		
Arguments	<i>metaclass</i>	The metaclass of the class being parsed.	
	<i>option</i>	The <code>defclass</code> option name.	
	<i>value</i>	The tail of the <code>defclass</code> option form.	

Values	<i>initargs</i>	A plist of initargs describing the option.
Description		The generic function <code>process-a-class-option</code> describes how the value of a class option is parsed. It is called at <code>defclass</code> macroexpansion time. By default LispWorks parses class options as defined in AMOP, but you need to supply a method if you need class options with different behavior. <i>initargs</i> should be a plist of class initargs and values. These are added to any other initargs for the class.

Example	<pre>(defmethod clos:process-a-class-option ((class m1) (name (eql :title)) value) (unless (and value (null (cdr value))) (error "m1 :title must have a single value.")) (list name (car value)))</pre> <pre>(defclass my-titled-class () () (:metaclass m1) (:title "Initial Title"))</pre>
---------	---

If the value is not to be evaluated, the method would look like this:

```
(defmethod clos:process-a-class-option
  ((class m1)
   (name (eql :title))
   value)
  (unless (and value (null (cdr value)))
    (error "m1 :title must have a single value."))
  `(,name ',value))
```

Now suppose we want an option whose value is a list of titles:

```
(defclass m2 (standard-class)
  ((titles-list :initarg :list-of-possible-titles)))
```

If the titles are to be evaluated, add a method like this:

```
(defmethod clos:process-a-class-option
  ((class m2)
   (name (eql :list-of-possible-titles))
   value)
  (list name `(list ,@value)))
```

Or, if the titles should not be evaluated, add a method like this:

```
(defmethod clos:process-a-class-option
  ((class m2)
   (name (eql :list-of-possible-titles))
   value)
  (list name `',value))

(defclass my-multi-titled-class ()
  ()
  (:metaclass m2)
  (:list-of-possible-titles
   "Initial Title 1"
   "Initial Title 2"))
```

See also **defclass**
 process-a-slot-option

process-a-slot-option

Generic Function

Summary	Describes how a defclass slot option is parsed.	
Package	clos	
Signature	process-a-slot-option	<i>metaclass option value already-processed-other-options slot => processed-options</i>
Arguments	<i>metaclass</i>	The metaclass of the class being parsed.
	<i>option</i>	The slot option name.

	<i>value</i>	The value of the slot option.
	<i>already-processed-other-options</i>	A plist of initargs for non-standard options that have been processed already.
	<i>slot</i>	The whole slot description.
Values	<i>processed-options</i>	A plist of initargs.
Description		<p>The generic function <code>process-a-slot-option</code> describes how the value of a slot option is parsed. It is called at <code>defclass</code> macroexpansion time. By default LispWorks parses slot options as defined in AMOP, but you need to supply a method if you need slot options with different behavior.</p> <p><i>processed-options</i> should be a plist of slot initargs and values containing those from <i>already-processed-other-options</i> together with initargs for <i>option</i> as required. These are added to any other initargs for the slot.</p>

Example

```
(defclass extended-class (standard-class))

(defmethod clos:process-a-slot-option
  ((class extended-class) option value
   already-processed-options slot)
  (if (eq option :extended-slot)
      (list* :extended-slot
             value
             already-processed-options)
      (call-next-method)))

(defclass extended-direct-slot-definition
  (clos:standard-direct-slot-definition)
  ((extended-slot :initarg :extended-slot :initform
    nil)))

(defmethod clos:direct-slot-definition-class
  ((x extended-class) &rest initargs)
  'extended-direct-slot-definition)

(defclass test ()
  ((regular :initform 3)
   (extended :extended-slot t :initform 4))
  (:metaclass extended-class))
```

To add a slot option `:special-reader` whose value is a non-evaluated symbol naming a reader:

```
(defmethod clos:process-a-slot-option
  ((class my-metaclass) option value
   already-processed-options slot)
  (if (and (eq option :special-reader)
            (symbolp value))
      (list* :special-reader
             `',value already-processed-options)
      (call-next-method)))
```

To allow repeated `:special-reader` options which are combined into a list:

```
(defmethod clos:process-a-slot-option
    ((class my-metaclass) option value
     already-processed-options slot)
  (if (and (eq option :special-reader) (symbolp value))
      (let ((existing (getf
                      already-processed-options
                      :special-reader)))
        (if existing ; this is a quoted list of symbols
            (progn
              (setf (cdr (last (cadr existing))) (list
value)))
              already-processed-options)
            (list* :special-reader
                  `',(,value)
                  already-processed-options)))
      (call-next-method)))

```

set-clos-initarg-checking *Function*

Summary Switches initarg checking on or off in **make-instance**, **reinitialize-instance**, **change-class** and so on.

Package **clos**

Signature **set-clos-initarg-checking** *on* => *on*

Arguments *on* A generalized boolean.

Description The function **set-clos-initarg-checking** provides control over whether CLOS checks initialization arguments.
 Initializations affected include:

- Calls to **make-instance**
- Calls to **reinitialize-instance**
- Calls to **change-class**

- `call-next-method` to `update-instance-for-redefined-class` with extra keywords.

Calling `set-clos-initarg-checking` with a true value of `on` causes the above initializations to check their initargs. This is the initial state of LispWorks.

Initarg checking is switched off globally and dynamically by

```
(set-clos-initarg-checking nil)
```

- Notes
1. The effect of calling `set-clos-initarg-checking` can be overridden in a runtime by the `deliver` keyword argument `:clos-initarg-checking`. See the *LispWorks Delivery User Guide* for details.
 2. `set-clos-initarg-checking` supersedes

|             | <b>Function</b>                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------|
| Summary     | Switches CLOS initarg checking on or off. This function is deprecated.                                            |
| Package     | <code>clos</code>                                                                                                 |
| Signature   | <code>set-make-instance-initarg-checking on =&gt; on</code>                                                       |
| Arguments   | <code>on</code> A boolean.                                                                                        |
| Description | The deprecated function <code>set-make-instance-initarg-checking</code> switches CLOS initarg checking on or off. |

|                    |                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes              | <code>set-make-instance-initarg-checking</code> is deprecated. It is an alias for <code>set-clos-initarg-checking</code> .                                                                                            |
| Compatibility Note | In LispWorks 6.1 <code>set-make-instance-initarg-checking</code> affects CLOS initializations other than <code>make-instance</code> . For clarity, you should now use <code>set-clos-initarg-checking</code> instead. |
|                    | In LispWorks 6.0 <code>set-make-instance-initarg-checking</code> affects only <code>make-instance</code> .                                                                                                            |

| Arguments | <b>class-designator</b>              | The class to trace.                                                                                                                                                                     |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | Returns <code>t</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description | <p>Causes new instances of the class given by <i>class-designator</i> to be traced for the access modes given by <code>read</code>, <code>write</code> and <code>slot-names</code>.</p> <p>The keyword arguments control which type of access are traced, and provide preconditions for tracing, code to run before access, and how to print any trace output. They are interpreted as described for <code>trace-on-access</code>.</p> <p>This function, when used with the <code>:break</code> keyword, replaces the deprecated function <code>break-new-instances-on-access</code>.</p> |
| Example     | <pre>(trace-new-instances-on-access 'capi:display-pane                                :slot-names nil)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|             | <p>Suppose you have a bug whereby the slot <code>bar</code> of an instance of your class <code>foo</code> is incorrectly being set to a negative integer value. You could cause entry into the debugger at the point where the slot is set incorrectly by evaluating this form:</p> <pre>(clos:trace-new-instances-on-access   'foo   :slot-names '(bar)   :read nil   :when '(and (integerp (car *traced-arglist*))               (&lt; (car *traced-arglist*) 0))   :break t)</pre>                                                                                                     |
|             | <p>and running your program.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Values      | Returns <code>t</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                 |
| Description | <p>A useful debugging function which causes access to <i>instance</i> to invoke the trace facilities. Accesses include calls to <code>slot-value</code> and accessor functions defined by the class of <i>instance</i>.</p> <p>The keyword arguments control which type of access are traced, and provide preconditions for tracing, code to run before access, and how to print any trace output. They are similar to those supported by the <code>trace</code> macro (but note that these CLOS symbols are functions, so the keyword values are evaluated immediately, unlike in <code>trace</code>).</p> <p><i>read</i> controls whether reading slots is traced. The default is <code>t</code>.</p> |                                                 |

*write* controls whether writing slots is traced. The default is `t`.

*slot-names* controls which slots to trace access for. It can be a list of symbols which are the slot-names. The default value, `t`, means trace access to all slots.

*break* controls whether the debugger is entered when a traced slot in *instance* is accessed. When `nil`, the debugger is not invoked and messages are printed to `*trace-output*`. The default value is `nil`.

*when* is evaluated during slot access to determine whether any tracing should occur. The default value is `t`.

*process* is evaluated during slot access to determine whether any tracing should occur in the current process. The form should evaluate to either `nil` (meaning trace in all processes), a string naming the process in which tracing should occur (see `process-name`, `find-process-from-name`), or a list of strings naming the processes in which tracing should occur. The default value is `nil`.

*trace-output* is evaluated during slot access to determine the stream on which to print tracing messages. If this is `nil` then the value of `*trace-output*` is used. The default value is `nil`.

*entrycond* is evaluated during slot access to determine whether the default tracing messages should be printed.

*eval-before* is a list of forms which are evaluated during slot access.

*before* is a list of forms which are evaluated during slot access. The first value returned by each form is printed.

*backtrace* controls what kind of backtrace to print. If this is `nil` then no backtrace is printed, and this is the default value. Otherwise it can be any of the following values:

`:quick` Like the `:bq` debugger command.

`t` Like the `:b` debugger command.

**:verbose** Like the `:b :verbose` debugger command.

**:bug-form** Like the `:bug-form` debugger command.

Other instances of the same class are unaffected and you can remove the trace by calling `untrace-on-access`.

The variable `*traced-arglist*` is bound to a list of arguments for the slot access during evaluation of the options above, that is (*instance slot-name*) when reading a slot and (*new-value instance slot-name*) when writing a slot.

A common use of this function is to find where a slot is being changed in a complex program.

This function, when called with `:break t`, replaces the deprecated function `break-on-access`.

## unbreak-new-instances-on-access

*Function*

Summary      Removes the trapping installed by `break-new-instances-on-access`. Note that this function is deprecated.

Package      `clos`

Signature      `unbreak-new-instances-on-access class-designator => t`

Arguments      `class-designator` The class whose trap you want to remove.

Values      Returns `t`.

Description      Removes the trapping installed by `break-new-instances-on-access`. Note that this function is deprecated. You should now use `untrace-new-instances-on-access` instead.

See also [`untrace-new-instances-on-access`](#)

## **unbreak-on-access** *Function*

Summary Removes the trapping installed by `break-on-access`. Note that this function is deprecated.

Package `clos`

Signature `unbreak-on-access instance`

Arguments `instance` A class instance

Values Returns `t`.

Description Removes any break installed on `instance` by `break-on-access`. See `untrace-on-access` for details.

**Note:** this function is deprecated. You should now use `untrace-on-access` instead.

See also [`untrace-on-access`](#)

## **untrace-new-instances-on-access** *Function*

Summary Removes the tracing installed by `trace-new-instances-on-access`.

Package `clos`

Signature `untrace-new-instances-on-access class-designator => t`

Arguments `class-designator` The class whose trap you want to remove.

Values Returns `t`.

## The COMM Package

This chapter provides reference entries for the functions in the `comm` package.

The `comm` package provides the TCP/IP interface. TCP/IP sockets can be used to communicate between processes and machines. The TCP/IP mechanism allows LispWorks to connect to or implement a server. It also allows using Secure Sockets Layer (SSL) processing in the socket.

An overview of this functionality is in Chapter 21, “TCP/IP socket communication and SSL”.

Before the interface can be used the module “`comm`” must be loaded using

```
(require "comm")
```

| attach-ssl | <i>Function</i>                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------|
| Summary    | Attaches SSL to a socket stream.                                                                                        |

| Values      | <i>ssl</i>                    | A foreign pointer of type <b>ssl-pointer</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description |                               | <p>The function <b>attach-ssl</b> attaches SSL to the socket-stream socket-stream.</p> <p>The allowed values and meaning of the keyword arguments are as described for <b>socket-stream</b>.</p> <p>Note that <b>attach-ssl</b> is used by</p> <pre>(make-instance 'comm:socket-stream :ssl-ctx ...)</pre> <p>and by</p> <pre>(comm:open-tcp-stream ... :ssl-ctx ...)</pre> <p>but you can also call it explicitly.</p> <p>Before starting to create objects, <b>attach-ssl</b> ensures the SSL library (by calling <b>ensure-ssl</b>) and calls <b>do-rand-seed</b> to seed the Pseudo Random Number Generator (PRNG), so normally you do not need to worry about these.</p> <p>If <i>ssl-ctx</i> is a symbol, it creates the <b>SSL_CTX</b> and calls <i>ctx-configure-callback</i> if this is non-nil. If <i>ssl-ctx</i> is not a <b>ssl-pointer</b>, it creates the <b>SSL</b> object, calls <i>ssl-configure-callback</i> if this is non-nil, and sets the ACCEPT/CONNECT state if the value of <i>ssl-side</i> is not <b>:both</b>. Then it uses <b>SSL_set_fd</b> to attach the</p> |

`ssl` to the socket, and records this in the socket stream. It returns the `ssl`.

The default value of `ssl-ctx` is `t` and the default value of `ssl-side` is `:server`.

When a `socket-stream` is closed, `detach-ssl` is called with `:retry-count nil`, which, if the stream is attached to SSL, calls `SSL_shutdown` and then frees the object (or objects) that were automatically allocated.

If SSL is already attached to `socket-stream` then `attach-ssl` signals an error.

See also      `detach-ssl`

## connect-to-tcp-server *Function*

Summary      Attempts to connect to a socket on a server.

Package      `comm`

Signature      `connect-to-tcp-server host service &key errorp timeout local-address local-port keepalive nodelay => handle`

Arguments

|                            |                                                                                 |
|----------------------------|---------------------------------------------------------------------------------|
| <code>host</code>          | An integer or string or an <code>ipv6-address</code> object.                    |
| <code>service</code>       | A string or a fixnum.                                                           |
| <code>errorp</code>        | A boolean.                                                                      |
| <code>timeout</code>       | A positive number, or <code>nil</code> .                                        |
| <code>local-address</code> | <code>nil</code> , an integer, a string or an <code>ipv6-address</code> object. |
| <code>local-port</code>    | <code>nil</code> , a string or a fixnum.                                        |
| <code>nodelay</code>       | A generalized boolean.                                                          |
| <code>keepalive</code>     | A generalized boolean.                                                          |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                   |

| Description | <p>The function <code>connect-to-tcp-server</code> attempts to connect to a socket on a server and returns a handle for the connection if successful. This handle can then be used as the socket when making a <code>socket-stream</code>.</p> <p>The server machine to connect to is given by <i>hostname</i>, which can be one of the following:</p> <ul style="list-style-type: none"> <li>• A string naming the host, for example<br/><code>"www.nowhere.com"</code></li> <li>• A string providing the IP address, for example<br/><code>"204.71.177.75"</code> or <code>"2001:500:2f::f"</code></li> <li>• An integer IP address in network order, for example<br/><code>#xCC47B14B</code></li> <li>• An <code>ipv6-address</code> object.</li> </ul> <p>The name of the service to provide is given by <i>service</i>. If <i>service</i> is a string, the location of the file specifying the names of the services available varies, but typically on Windows 98 it is called <code>SERVICES</code> and is stored in the Windows directory., and on Windows NT-based systems it is the file</p> <pre>%SystemRoot%\system32\drivers\etc\SERVICES</pre> <p>The service can also be a fixnum representing the port number of the desired connection.</p> <p>If <i>errorp</i> is <code>nil</code>, failure to connect (possibly after <i>timeout</i> seconds) returns <code>nil</code>, otherwise an error is signaled.</p> <p><i>timeout</i> specifies a connection timeout. <code>connect-to-tcp-server</code> waits for at most <i>timeout</i> seconds for the TCP connection to be made. If <i>timeout</i> is <code>nil</code> it waits until the connection attempt succeeds or fails. On failure, <code>connect-to-tcp-server</code> signals an error or returns <code>nil</code> according to the value of <i>errorp</i>. To provide a timeout for reads after the connection</p> |                                                                   |

is made, see *read-timeout* in `socket-stream`. The default value of *timeout* is `nil`.

If *local-address* is `nil` then the operating system chooses the local address of the socket. Otherwise the value is interpreted as for *hostname* and specifies the local address of the socket. The default value of *local-address* is `nil`.

If *local-port* is `nil` then the operating system chooses the local port of the socket. Otherwise the string or fixnum value is interpreted as for *service* and specifies the local port of the socket. The default value of *local-port* is `nil`.

If *keepalive* is true, `SO_KEEPALIVE` is set on the socket. The default value of *keepalive* is `nil`.

If *nodelay* is true, `TCP_NODELAY` is set on the socket. The default value of *nodelay* is `t`.

- Notes
1. On Unix the name of the service can normally be found in `/etc/services`. If it is not there, the manual entry for services can be used to find it.
  2. In most situations, `open-tcp-stream`, which returns a stream rather than a handle, is the more convenient interface. `connect-to-tcp-server` is useful when want to associate further information with the stream. You can define a subclass of `socket-stream`, connect using `connect-to-tcp-server`, and call `make-instance` with your subclass, passing the *handle* as the socket.

|             |                                                                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signature   | <code>destroy-ssl <i>ssl-pointer</i></code>                                                                                                                      |
| Arguments   | <i>ssl-pointer</i> A foreign pointer of type <code>ssl-pointer</code> .                                                                                          |
| Description | The function <code>destroy-ssl</code> frees the <code>SSL</code> pointed to by <i>ssl-pointer</i> and also frees any LispWorks cached values associated with it. |
| See also    | <code>ssl-pointer</code>                                                                                                                                         |

## destroy-ssl-ctx

*Function*

|             |                                                                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Frees a <code>SSL_CTX</code> .                                                                                                                                               |
| Package     | <code>comm</code>                                                                                                                                                            |
| Signature   | <code>destroy-ssl-ctx <i>ssl-ctx-pointer</i></code>                                                                                                                          |
| Arguments   | <i>ssl-ctx-pointer</i> A foreign pointer of type <code>ssl-ctx-pointer</code> .                                                                                              |
| Description | The function <code>destroy-ssl-ctx</code> frees the <code>SSL_CTX</code> pointed to by <i>ssl-ctx-pointer</i> and also frees any LispWorks cached values associated with it. |

| <i>retry-count</i>   | A non-negative integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>retry-timeout</i> | A non-negative real.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Description          | <p>The function <code>detach-ssl</code> detaches the SSL from the socket-stream <i>socket-stream</i>. If <i>socket-stream</i> is not attached to an SSL, <code>detach-ssl</code> just returns immediately. Otherwise, it detaches the SSL from <i>socket-stream</i>, tries to shut down the SSL cleanly, and then frees the objects that were allocated by <code>attach-ssl</code>.</p> <p><i>retry-count</i> specifies how many additional times to call <code>SSL_shutdown</code> after the second to attempt to get a successful shutdown. The default value of <i>retry-count</i> is 5.</p> <p><i>retry-timeout</i> specifies the time in seconds to wait between each of the calls to <code>SSL_shutdown</code>. If it fails to get a successful shutdown after these attempts, <code>detach-ssl</code> signals an error. The default value of <i>retry-timeout</i> is 0.1.</p> <p>Note that the shutdown calls happen after the SSL has been detached from <i>socket-stream</i> as far as LispWorks is concerned, so if an error occurs at this point and is aborted, <i>socket-stream</i> can be used in <code>attach-ssl</code> again (assuming that the peer can cope with this situation).</p> <p>If <i>retry-count</i> is <code>nil</code>, <code>detach-ssl</code> does not try to get a successful shutdown call. This value is used when the stream is closed, but should not be used normally.</p> |

| <b>do-rand-seed</b> |                                                 |
| Summary             | Calls the SSL function <code>RAND_seed</code> . |
| Package             | <code>comm</code>                               |
| Signature           | <code>do-rand-seed</code>                       |

|             |                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments   | <code>do-rand-seed</code> takes no arguments.                                                                                                                                                                                                                                                                                                                                                |
| Values      | <code>do-rand-seed</code> returns no values.                                                                                                                                                                                                                                                                                                                                                 |
| Description | <p>The function <code>do-rand-seed</code> calls the SSL function <code>RAND_seed</code> with some suitable value, which is dependent in a non-trivial way on the current time, the history of the current process and the history of the machine it is running on.</p> <p>If the machine that it runs on has the file <code>/dev/urandom</code>, <code>do-rand-seed</code> does nothing.</p> |

| Description         | <p>The function <code>ensure-ssl</code> initializes SSL. If it was already called in the image, <code>ensure-ssl</code> does nothing. Otherwise it loads the library, calls <code>SSL_library_init</code>, calls <code>SSL_load_error_strings</code> and performs internal initializations.</p> <p>If <i>already-done</i> is true, <code>ensure-ssl</code> does only the internal initializations. The default value of <i>already-done</i> is <code>nil</code>.</p> <p>If <i>library-path</i> is passed, it needs to be either a string, specifying one library, or a list of strings specifying multiple libraries. The default value of <i>library-path</i> is platform-specific.</p> |                     |                                |                     |                        |

The initial default value is described in “Loading the OpenSSL libraries” on page 295. This default may be changed by calling `set-ssl-library-path`.

|             | <b>get-host-entry</b>       |                                                                                                                                                                                                                                                                                                    |
| Summary     |                             | Returns address (IPv6 and IPv4) or name information about a given host.                                                                                                                                                                                                                            |
| Package     |                             | <code>comm</code>                                                                                                                                                                                                                                                                                  |
| Signature   |                             | <b>get-host-entry</b> <i>host &amp;key fields ipv6 v4mapped addrconfig numerichost avoid-reverse-lookup =&gt; field-values</i>                                                                                                                                                                     |
| Arguments   | <i>host</i>                 | A number or a string.                                                                                                                                                                                                                                                                              |
|             | <i>fields</i>               | A list of keywords.                                                                                                                                                                                                                                                                                |
|             | <i>ipv6</i>                 | <code>nil</code> , <code>t</code> or the keyword <code>:any</code> .                                                                                                                                                                                                                               |
|             | <i>avoid-reverse-lookup</i> | A generalized boolean.                                                                                                                                                                                                                                                                             |
|             | <i>v4mapped</i>             | A boolean.                                                                                                                                                                                                                                                                                         |
|             | <i>addrconfig</i>           | A boolean.                                                                                                                                                                                                                                                                                         |
|             | <i>numerichost</i>          | A boolean.                                                                                                                                                                                                                                                                                         |
| Values      | <i>field-values</i>         | Values, one for each field.                                                                                                                                                                                                                                                                        |
| Description |                             | The function <code>get-host-entry</code> returns address or name information about the given host. By default, it tries to find addresses both of IPv6 and IPv4. It uses whatever host naming services are configured on the current machine. <code>nil</code> is returned if the host is unknown. |

The *host* argument can be one of the following:

- a name string, for example "`www.foobar.com`"
- a dotted inet address string, for example "`209.130.14.246`"
- a integer representing the inet address, for example `#xD1820EF6`

The *fields* argument is a list of keywords describing what information to return for the host. If `get-host-entry` succeeds, it returns multiple values, one value for each field specified. The following fields are allowed:

- |                              |                                         |
|------------------------------|-----------------------------------------|
| <code>:address</code>        | The primary IP address.                 |
| <code>:ipv6-address</code>   | The primary IPv6 address.               |
| <code>:ipv4-address</code>   | The primary IPv4 address.               |
| <code>:addresses</code>      | A list of all the IP addresses.         |
| <code>:ipv6-addresses</code> | A list of all the IPv6 addresses, only. |
| <code>:ipv4-addresses</code> | A list of all the IPv4 addresses, only. |
| <code>:name</code>           | The primary name as a string.           |
| <code>:aliases</code>        | The alias names as a list of strings.   |

IPv4 addresses are returned as integers and IPv4 addresses are returned as objects of type `ipv6-address`.

If *ipv6* is `nil` or `t` the search is restricted to one family only IPv4 or IPv6. The default value of *ipv6* is `:any`, meaning that addresses in both families are returned. If the argument *host* is a string, that has a similar effect to using the family-specific keywords, but it may be faster. For example, these two calls returns the same addresses (possibly in a different order):

```
(get-host-entry "hostname"
 :fields '(:ipv6-addresses))

(get-host-entry "hostname"
 :fields '(:addresses) :ipv6 t)
```

If *host* is an address of the other type, that is integer with *ipv6 t* or *ipv6-address* with *ipv6 nil*, then `get-host-entry` first tries to do a reverse lookup to find the name of the host, and then looks for the values as if it was called with this name as the host.

When *avoid-reverse-lookup* is non-nil, `get-host-entry` avoids doing reverse lookup if *host* is a string which specifies a valid address (either IPv6 or IPv4). The default value of *avoid-reverse-lookup* is *nil*, so by default it does the lookup.

The arguments *v4mapped*, *addrconfig* and *numerichost* have an effect only when *host* is a string. They define the flags `AI_V4MAPPED`, `AI_ADDRCONFIG` and `AI_NUMERICHOST` when doing the `getaddrinfo` call.

When *v4mapped* is *t*, the IPv6 addresses contain an IPv4 address mapped to IPv6 (:ffff:<IPv4>). The default value of *v4mapped* is *nil*.

When *addrconfig* is *t*, addresses of a family are returned only if the local system is configured to handle them. The default value of *addrconfig* is *nil*.

When *numerichost* is *t*, *host* is assumed to be a numeric address, either IPv4 if dotted notation or IPv6. If it is not, `get-host-entry` just returns *nil*. Using *numerichost* can speed up `get-host-entry`, because it prevents any DNS lookup. This has an effect only if *avoid-reverse-lookup* is non-nil. The default value of *numerichost* is *nil*.

## Notes

1. Although the results of `get-host-entry` are not cached by LispWorks, the Operating System might cache them.

2. When `get-host-entry` is passed a string specifying an IPv6 address, the address can be followed by '%' character and a scope ID. If the scope ID is a decimal number or a valid interface name on the local system, the resulting address contains the scope ID as a number.

**Examples**

```
CL-USER 16 > (comm:get-host-entry "www.altavista.com"
 :fields '(:address))
3511264349

CL-USER 17 > (comm:get-host-entry 3511264349
 :fields '(:name))
"altavista.com"

CL-USER 18 > (comm:get-host-entry "altavista.com"
 :fields '(:name
 :address
 :aliases))
"altavista.com"
3511264349
("www.altavista.com" "www.altavista.com")
```

**get-socket-address***Function*

|             |                                                                                               |                                                                            |

`socket-stream-address`

## **get-socket-peer-address** *Function*

Summary Returns the remote address and port number of a given socket.

Package `comm`

Signature `get-socket-peer-address socket -> address, port`

Arguments `socket` A socket handle.

Values `address` The remote host address of the socket or `nil` if not connected.

`port` The remote port number of the socket or `nil` if not connected.

Description The function `get-socket-peer-address` returns the remote address of a connected socket.

Notes Connected sockets have two addresses, local and remote.

|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ip-address-string</b> |                                                                                                                                                                                             |
| Summary                  | Returns the IP address string for an IP address. This can be either a dotted address for an integer representing an IPv4 address, or an IPv6 address string for <code>ipv6-address</code> . |
| Package                  | <code>comm</code>                                                                                                                                                                           |
| Signature                | <code>ip-address-string ip-address =&gt; string-ip-address</code>                                                                                                                           |
| Arguments                | <code>ip-address</code> An integer or an <code>ipv6-address</code> .                                                                                                                        |
| Values                   | <code>string-ip-address</code> A string, either dotted string format for an integer or an IPv6 string for <code>ipv6-address</code> .                                                       |
| Description              | The function <code>ip-address-string</code> converts its argument to a string in the standard dotted IP address notation <code>a.b.c.d</code> .                                             |

The function `ip-address-string` converts its argument to a string in the standard IP address notation. For an IPv4 address (supplied as an integer) this is the `a.b.c.d` notation. For IPv6 it is the standard IPv6 address notation (not including scope ID).

## **ipv6-address** *Type*

Summary      Represents IPv6 addresses.

Package      `comm`

Description      Objects of type `ipv6-address` represent an IPv6 address.

`ipv6-address` objects are normally created by `get-host-entry`. They can also be created by `parse-ipv6-address`.

`ipv6-address` can be used wherever an IP address is needed, most commonly `open-tcp-stream`, except that `ipv6-address-string` takes only an IPv4 address (that is, integers).

`ipv6-address` may contain a scope ID, which is not really part of the address, but is needed for using local addresses.

                  `ipv6-address-p`  
                  `parse-ipv6-address`

## **ipv6-address-p** *Function*

Summary      The predicate for objects of type `ipv6-address`.

Package      `comm`

|             |                                                                                                                                         |                |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|----------------|
| Signature   | <code>ipv6-address-p <i>object</i> =&gt; <i>result</i></code>                                                                           |                |
| Arguments   | <i>object</i>                                                                                                                           | A Lisp object. |
| Values      | <i>result</i>                                                                                                                           | A boolean.     |
| Description | The function <code>ipv6-address-p</code> is the predicate for whether its argument <i>object</i> is of type <code>ipv6-address</code> . |                |
| See also    | <code>ipv6-address</code>                                                                                                               |                |

| Values                | <code>ssl-ctx-ptr</code> A foreign pointer of type <code>ssl-ctx-pointer</code> .                                                                                                                                                                                                                                                                                                                                        |                      |                                |                       |                                                                                         |
| Description           | <p>The function <code>make-ssl-ctx</code> first calls <code>ensure-ssl</code>, and returns a foreign pointer of type <code>ssl-ctx-pointer</code>.</p> <p>If the value of <code>ssl-ctx</code> is <code>t</code>, <code>:default</code>, <code>:v2</code>, <code>:v3</code>, <code>:v23</code> or <code>:tls-v1</code>, <code>make-ssl-ctx</code> creates a <code>SSL_CTX</code> object and returns a pointer to it.</p> |                      |                                |                       |                                                                                         |

The value of `ssl-ctx` can also be a foreign pointer of type `ssl-ctx-pointer`, in which case it is simply returned. If `ssl-ctx` is a foreign pointer of type `ssl-pointer`, then `make-ssl-ctx` signals an error.

The meaning of the keyword arguments `ssl-ctx` and `ssl-side` is as described for `socket-stream`. The default value of `ssl-ctx` is `t` and the default value of `ssl-side` is `:server`.

|             | <i>keepalive</i>              | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Values      | <i>stream-object</i>          | A socket stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Description |                               | <p>The function <code>open-tcp-stream</code> attempts to connect to a socket on a server and returns <i>stream-object</i> for the connection if successful. The server machine to connect to is given by <i>hostname</i>, which can be one of the following:</p> <ul style="list-style-type: none"> <li>• A string naming the host, for example<br/><code>"www.nowhere.com"</code></li> <li>• A string providing the IP address, for example<br/><code>"204.71.177.75"</code> or <code>"2001:500:2f::f"</code></li> <li>• An integer IP address in network order, for example<br/><code>#xCC47B14B</code></li> <li>• An <code>ipv6-address</code> object.</li> </ul> <p>The name of the service to provide is given by <i>service</i>. If <i>service</i> is a string, the location of the file specifying the names of the services available varies, but typically on Windows 98 it is called <code>SERVICES</code> and is stored in the <code>Windows</code> directory., and on Windows NT-based systems it is the file</p> |

```
%SystemRoot%\system32\drivers\etc\SERVICES
```

The *service* can also be a fixnum representing the port number of the desired connection.

The direction of the connection is given by *direction*. Its default value is `:io`. The element type of the connection is determined from *element-type*, and is `base-char` by default.

If *errorp* is `nil`, failure to connect (possibly after *timeout* seconds) returns `nil`, otherwise an error is signaled.

*timeout* specifies a connection timeout. `open-tcp-stream` waits for at most *timeout* seconds for the TCP connection to be made. If *timeout* is `nil` it waits until the connection attempt succeeds or fails. On failure, `open-tcp-stream` signals an error or returns `nil` according to the value of *errorp*. To provide a timeout for reads after the connection is made, see `read-timeout`. The default value of *timeout* is `nil`.

`read-timeout` specifies the read timeout of the stream. If it is `nil` (the default), the stream does not time out during reads, and these may hang. See `socket-stream` for more details. To provide a connection timeout, see *timeout*.

`write-timeout` is similar to `read-timeout`, but for writes. See `socket-stream` for more details.

`ssl-ctx`, `ctx-configure-callback` and `ssl-configure-callback` are interpreted as described for `socket-stream`. Unlike the other ways of creating a socket stream with SSL processing, `open-tcp-stream` does not take the `ssl-side` argument and always uses the value `:client`.

If *local-address* is `nil` then the operating system chooses the local address of the socket. Otherwise the value is interpreted as for `hostname` and specifies the local address of the socket. The default value of *local-address* is `nil`.

If *local-port* is `nil` then the operating system chooses the local port of the socket. Otherwise the string or fixnum value is

interpreted as for *service* and specifies the local port of the socket. The default value of *local-port* is `nil`.

If *keepalive* is true, `SO_KEEPALIVE` is set on the socket. The default value of *keepalive* is `nil`.

If *nodelay* is true, `TCP_NODELAY` is set on the socket. The default value of *nodelay* is `t`.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | On Unix the name of the service can normally be found in <code>/etc/services</code> . If it is not there, the manual entry for services can be used to find it.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Example  | The following example opens an HTTP connection to a given host, and retrieves the root page:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## openssl-version *Function*

|         |                                                    |
|---------|----------------------------------------------------|
| Summary | Returns the version of the loaded OpenSSL library. |
|---------|----------------------------------------------------|

|             |                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Package     | <code>comm</code>                                                                                                                                                          |
| Signature   | <code>openssl-version &amp;optional what =&gt; result</code>                                                                                                               |
| Arguments   | <code>what</code> One of the keywords <code>:version</code> , <code>:directory</code> , <code>:platform</code> , <code>:cflags</code> and <code>:built-on</code> .         |
| Values      | <code>result</code> A string.                                                                                                                                              |
| Description | The function <code>openssl-version</code> returns a string specifying the version of the loaded OpenSSL library.<br><br>The argument <code>what</code> takes these values: |
|             | <code>:version</code> <code>result</code> is the version string, which looks like:<br>"OpenSSL 0.9.7i 14 Oct 2005" or<br>"OpenSSL 0.9.8a 11 Oct 2005"                      |
|             | <code>:built-on</code> Returns a string specifying when it was built.                                                                                                      |
|             | <code>:directory</code> Returns where OpenSSL thinks it is installed.                                                                                                      |
|             | <code>:platform</code> Returns OpenSSL's idea of which platforms it is.                                                                                                    |
|             | <code>:cflags</code> The compilation command.                                                                                                                              |
|             | The default value of <code>what</code> is <code>:version</code> .                                                                                                          |
| See also    | <code>ensure-ssl</code>                                                                                                                                                    |

| <b>parse-ipv6-address</b> | <i>Function</i>                     |
|---------------------------|-------------------------------------|
| Summary                   | Parses a string as an IPv6 address. |
| Package                   | <code>comm</code>                   |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                             |

| Description | <p>The function <code>parse-ipv6-address</code> parses its argument string as an IPv6 address if possible, otherwise it returns <code>nil</code>.</p> <p><i>start</i> and <i>end</i> specify the subsequence of <i>string</i> to parse. The default value of <i>start</i> is 0. The default value of <i>end</i> is <code>nil</code>, meaning the length of <i>string</i>.</p> <p><i>trim-whitespace</i> is a boolean specifying that leading and trailing whitespace characters may be ignored. Note that the address itself must not contain any whitespace. The default value of <i>trim-whitespace</i> is t.</p> <p>The address has to be in either standard IPv6 address notation, or dotted-quad notation. It can have the standard simplifications.</p> <p>In addition, the address may be followed by a '%' character and a scope ID. If the scope ID is a string of decimal characters, it is read as a decimal number, otherwise it is taken as-is. The address may also be followed by a '/' and a prefix length in decimal format. The result <code>ipv6-address</code> object remembers the prefix length and prints it when the object is printed, but it does not affect the address otherwise.</p> <p>If the syntax of the string <i>string</i> is correct, <code>parse-ipv6-address</code> constructs the <code>ipv6-address</code> object and returns it. It does not perform any address resolution.</p> |                                             |

| Summary         | An interface to the SSL <code>PEM_read_bio_*</code> functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Package         | <code>comm</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Signature       | <code>pem-read <i>thing-to-read</i> <i>filename</i> &amp;key <i>pass-phrase</i> <i>callback</i> <i>errorp</i> =&gt; <i>result</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Arguments       | <p><i>thing-to-read</i>      A string.</p> <p><i>filename</i>            A pathname designator.</p> <p><i>pass-phrase</i>        A string, or <code>nil</code>.</p> <p><i>callback</i>            A function designator, or <code>nil</code>.</p> <p><i>errorp</i>             A generalized boolean.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Values          | <i>result</i> A foreign pointer or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description     | <p>The function <code>pem-read</code> is an interface to the <code>PEM_read_bio_*</code> set of functions. See the manual entry for <code>pem</code> for specifications of these functions.</p> <p><i>thing-to-read</i> defines which function is required. <code>pem-read</code> concatenates <i>thing-to-read</i> with the string " <code>PEM_read_bio_</code>" to form the name of the <code>pem</code> function to call.</p> <p><i>filename</i> specifies the file to load.</p> <p>If <i>pass-phrase</i> is non-nil, it must be a string, which is passed to the <code>pem</code> function. The default value of <i>pass-phrase</i> is <code>nil</code>.</p> <p>If <i>callback</i> is non-nil, it must be a function with signature:</p> <pre><code>callback <i>maximum-length</i> <i>rwflag</i> =&gt; <i>pass-phrase</i></code></pre> <p>where <i>maximum-length</i> is an integer, <i>rwflag</i> is a boolean and <i>pass-phrase</i> is the pass-phrase to use. The default value of <i>callback</i> is <code>nil</code>, but you cannot pass non-nil values for both <i>pass-phrase</i> and <i>callback</i>.</p> |

If it succeeds, `pem-read` returns a foreign pointer to the structure that was returned by the `pem` function. If `pem-read` fails, if `errorp` is non-nil it signals an error, otherwise it returns `nil`. The default value of `errorp` is `nil`.

## **read-dhparams** *Function*

**Summary**     Reads or uses cached SSL DH parameters.

**Package**     `comm`

**Signature**     `read-dhparams filename &key pass-phrase callback errorp force => dh-ptr`

**Arguments**     `filename`         A pathname designator.

`pass-phrase`     A string, or `nil`.

`callback`      A function designator, or `nil`.

`errorp`        A generalized boolean.

`force`         A generalized boolean.

**Values**        `dh-ptr`      A foreign pointer or `nil`.

**Description**     The function `read-dhparams` reads or uses cached DH parameters.

`filename` specifies the file to check.

Unless `force` is true, `read-dhparams` checks if the file `filename` has already been loaded, and if it has been loaded, uses the cached value.

If `force` is true, or if there is no cached value for `filename`, `read-dhparams` loads the file by calling `pem-read` with `thing-to-read` argument "DHparams", `pass-phrase`, `callback` and `errorp`. `read-dhparams` caches and returns a foreign pointer to the

resulting DH structure (that is, a pointer corresponding to the C type `DH*`).

If `read-dhparams` fails to load the file *filename*, if `errorp` is true it signals an error, otherwise it returns `nil`. The default value of `errorp` is `t`.

## server-terminate *Function*

Summary Terminates a server.

Package `comm`

Signature `server-terminate server => result`

Arguments `server` A `mp:process` object.

Values `result` A boolean.

Description The function `server-terminate` terminates the server process `server`.

`server` must be a process which is the result of a call to `start-up-server`. `server-terminate` terminates it, and frees all the associated resources.

`server-terminate` returns `t` if the server was still active when it was called, otherwise it returns `nil`. It can be called repeatedly on the same server, and can be used as a predicate to check whether the server really went away.

Notes In LispWorks 6.0 and earlier versions, `process-kill` is the way to terminate servers. This is deprecated, because it may leave some value in an invalid state.

| Summary     |                      | Sets the verification mode for CTX.                                                                                                                                                                                                                                     |
| Package     |                      | <code>comm</code>                                                                                                                                                                                                                                                       |
| Signature   |                      | <code>set-verification-mode ssl-ctx ssl-side mode &amp;optional<br/>callback</code>                                                                                                                                                                                     |
| Arguments   | <i>ssl-ctx</i>       | A foreign pointer of type <code>ssl-pointer</code> or<br><code>ssl-ctx-pointer</code> .                                                                                                                                                                                 |
|             | <i>ssl-side</i>      | <code>:server</code> or <code>:client</code> .                                                                                                                                                                                                                          |
|             | <i>mode</i>          | An integer, one of the symbols <code>:never</code> ,<br><code>:always</code> , <code>:once</code> , or a list of keywords.                                                                                                                                              |
|             | <i>callback</i>      | A foreign function.                                                                                                                                                                                                                                                     |
| Values      | <i>result</i>        | A list of symbols.                                                                                                                                                                                                                                                      |
| Description |                      | The function <code>set-verification-mode</code> sets the verification mode for CTX according to arguments <i>ssl-side</i> and <i>mode</i> .<br><br>When <i>ssl-side</i> is <code>:server</code> , <i>mode</i> can be:                                                   |
|             | An integer           | <i>mode</i> is passed directly to <code>SSL_set_verify</code> or <code>SSL_CTX_set_verify</code> .                                                                                                                                                                      |
|             | <code>:never</code>  | The server will not send a client certificate request to the client, so the client will not send a certificate.                                                                                                                                                         |
|             | <code>:always</code> | The server sends a client certificate request to the client. The certificate returned (if any) is checked. If the verification process fails, the TLS/SSL handshake is immediately terminated with an alert message containing the reason for the verification failure. |

|                                                              |                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Description           | <p>The function <b>set-ssl-ctx-dh</b> sets the DH parameters for a <b>SSL_CTX</b>.<br/> <i>ssl-ctx</i> can be either a foreign pointer of type <b>ssl-ctx-pointer</b> or a foreign pointer of type <b>ssl-pointer</b>.</p> <p>The value is to use is specified by one of the parameters <i>dh</i>, <i>filename</i>, <i>func</i> or <i>filename-list</i>.</p> <p>If <i>dh</i> is non-nil, it must be a foreign pointer to a DH (corresponding to the C type <b>DH*</b>), and this DH is used as-is. The default value of <i>dh</i> is <b>nil</b>.</p> <p>Otherwise, if <i>filename</i> is non-nil, it must be a pathname designator for a file containing DH parameters, which is loaded (by <b>read-dhparams</b>) and then used. In this case, <i>pass-phrase</i> and <i>callback</i> can be used, and are passed to <b>pem-read</b>.</p> <p>Otherwise, if <i>func</i> is non-nil, it must be a function with signature:</p> |

```
func is-export keylength => dh-ptr
```

where *is-export* is a boolean, *keylength* is an integer, and *dh-ptr* is a pointer to an appropriate DH structure. **set-ssl-ctx-dh** installs *func* as the DH callback.

Otherwise (that is, if each of *dh*, *filename* and *func* are **nil**) then *filename-list* must be a non-nil association list of keylengths and filenames, sorted by the keylengths in ascending order (that is, larger keylengths are towards the end of the list). **set-ssl-ctx-dh** installs a DH callback which when called finds the first keylength which is equal or bigger than the required keylength, loads the associated file (by calling **read-dhparams**), and returns it. It also loads the first file of the list immediately.

*result* is **t** on success, **nil** otherwise.

| Description           | The function <code>set-ssl-ctx-password-callback</code> sets the password for a <code>SSL_CTX</code> , either to a callback or a password.<br><br><code>ssl-ctx</code> should be a foreign pointer of type <code>ssl-ctx-pointer</code> .<br><br>If <code>callback</code> is non-nil, it must be a function with signature: |                      |                    |                       |                                              |                       |                                 |

**callback *maximum-length rwflag => result***

where *maximum-length* is an integer, *rwflag* is a boolean and *result* is a string. The default value of *callback* is `nil`.

If *password* is non-`nil` and *callback* is `nil`, a callback is installed that simply returns *password*. The default value of *password* is `nil`.

If both *callback* and *password* are `nil`, `set-ssl-ctx-password-callback` signals an error.

## **set-ssl-library-path** *Function*

Summary      Sets the SSL library path.

Package      **comm**

Signature      **set-ssl-library-path *library-path***

Arguments      *library-path*      A string or a list of strings.

Description      The function **set-ssl-library-path** sets the SSL library path.

*library-path* should a string or a list of strings. Each string specifies a library to load. The libraries are loaded in the order they are in the list.

Note that in contrast to `ensure-ssl`, the effect of `set-ssl-library-path` persists after saving and restarting the image.

`:ssl-configure-callback`

A function designator or `nil`.

Accessors

`socket-stream-socket`  
`stream:stream-read-timeout`  
`stream:stream-write-timeout`

Description

The class `socket-stream` implements a buffered stream connected to a socket. The socket handle, specified by `:socket`, and the direction, specified by `:direction`, must be passed for a meaningful stream to be constructed. Common Lisp input functions such as `read-char` will see `end-of-file` if the other end of the socket is closed.

The `:element-type` keyword determines the expected element type of the stream traffic. However, stream input and output functions for character and binary data generally work in the obvious way on a `socket-stream` with `element-type base-char`, `(unsigned-byte 8)` or `(signed-byte 8)`. For example, `read-sequence` can be called with a string buffer and a binary `socket-stream`: the character data is constructed from the input as if by `code-char`. Similarly `write-sequence` can be called with a string buffer and a binary `socket-stream`: the output is converted from the character data as if by `char-code`. Also, 8-bit binary data can be read and written to a `base-char` `socket-stream`.

All standard stream I/O functions except for `write-byte` and `read-byte` have this flexibility.

The `:read-timeout` initarg specifies the read timeout in seconds, or is `nil`, meaning there are no timeouts during reads (this is the default).

The `read-timeout` property is intended for use when a socket connection might hang during a call to any Common Lisp input function. The `read-timeout` can be set by `make-instance` or by `open-tcp-stream`. It can also be modified by `(setf stream:stream-read-timeout)`. When `read-timeout` is `nil`, there is no timeout during reads and the call may hang.

When *read-timeout* is not `nil`, and there is no input from the socket for more than *read-timeout* seconds, any reading function returns `end-of-file`. The *read-timeout* does not limit the time inside `read`, but the time between successful extractions of data from the socket. Therefore, if the reading needs several rounds it may take longer than *read-timeout*.

Using `(setf stream:stream-read-timeout)` on the stream while it is inside a read function has undefined effects. However, the `setf` function can be used between calls to read functions. The *read-timeout* property of a stream can be read by  
`(stream:stream-read-timeout stream)`

The `:write-timeout` initarg specifies the write timeout in seconds, or is `nil`, meaning that there are no timeouts during writes (this is the default).

The *write-timeout* property is similar to *read-timeout*, but for write operations. If flushing the stream buffer takes too long then `error` is called.

The keyword arguments `:ssl-ctx`, `:ssl-side`, `:ctx-configure-callback` and `:ssl-configure-callback` can be passed to create and configure socket streams with SSL processing.

`ssl-ctx`, if non-nil, specifies that the stream uses SSL and further specifies the `SSL_CTX` object to use. The value of `ssl-ctx` can be a symbol which, together with `ssl-side`, specifies which protocol to use. The value `t` or `:default` means use the default, which is currently the same as `:v23`. The values `:v2`, `:v3`, `:v23` and `:tls-v1` are mapped to the `SSLv2_*`, `SSLv3_*`, `SSLv23_*` and `TLSv1_*` methods respectively. With these symbol values of `ssl-ctx`, LispWorks makes a new `SSL_CTX` object and uses it and frees it when the stream is closed.

The value of `ssl-ctx` can also be a foreign pointer of type `ssl-ctx-pointer` (which corresponds to the C type `SSL_CTX*`). This is used and is not freed when the stream is closed. Also

an SSL object is made and used, and this object is freed when the stream is closed. The foreign pointer may be a result of a call to `make-ssl-ctx`, but it can also a result of user code, provided that it points to a valid `ssl_ctx` and has the type `ssl-ctx-pointer`.

The value of `ssl-ctx` can also be a foreign pointer of type `ssl-pointer` (which corresponds to the C type `SSL*`). This specifies the SSL to use. This maybe a result of a call to `ssl-new` but can also be the result of user code, provided that it points to a valid SSL object and has the type `ssl-pointer`. The SSL is used and is not freed when the stream is closed.

When you pass a `ssl-ctx-pointer` or a `ssl-pointer` foreign pointer as the `ssl-ctx` argument, it must have already been set up correctly.

`ssl-side` specifies which side the socket stream is. The value of `ssl-side` is used in two cases:

- When a new `ssl_ctx` object is created, it is used to select the method:
 

```
:client => *_client_method
:server => *_server_method
:both => *_method
```
- When a new SSL object is created, when `ssl-side` is either `:client` or `:server`, LispWorks calls `SSL_set_connect_state` or `SSL_set_accept_state` respectively.

If the value of `ssl-ctx` is a `ssl-pointer`, `ssl-side` is ignored.

`ctx-configure-callback` specifies a callback, a function which takes a foreign pointer of type `ssl-ctx-pointer`. This is called immediately after a new `ssl_ctx` is created. If the value of `ssl-ctx` is not a symbol, `ctx-configure-callback` is ignored.

`ssl-configure-callback` specifies a callback, a function which takes a foreign pointer of type `ssl-pointer`. This is called

immediately after a new SSL is created. If the value of `ssl-ctx` is a `ssl-pointer`, `ssl-configure-callback` is ignored.

**Notes** The function `wait-for-input-streams` and `wait-for-input-streams-returning-first` are a convenient interface for waiting for input from socket streams. The standard I/O functions (`cl:read`, `cl:read-char` and so on) can also wait properly. You can also use `process-wait` and similar functions with `cl:listen` in the `wait-function`, but you will need to use `with-noticed-socket-stream`.

**Example** The following makes a bidirectional stream connected to a socket specified by `handle`.

```
(make-instance 'comm:socket-stream
 :socket handle
 :direction :io
 :element-type 'base-char)
```

This example creates a socket stream with a read-timeout:

```
(make-instance 'comm:socket-stream
 :handle handle
 :direction :input
 :read-timeout 42)
```

The following form illustrates character I/O in a binary `socket-stream`:

```
(with-open-stream (x
 (comm:open-tcp-stream
 "localhost" 80
 :element-type '(unsigned-byte 8)))
 (write-sequence (format nil "GET / HTTP/1.0~%~%") x)
 (force-output x)
 (let ((res (make-array 20 :element-type 'base-char)))
 (values (read-sequence res x) res)))
```

The following form illustrates binary I/O in a `base-char socket-stream`:

```
(with-open-stream (x
 (comm:open-tcp-stream
 "localhost" 80
 :element-type 'base-char))
 (write-sequence
 (map '(simple-array (unsigned-byte 8) 1)
 'char-code
 (format nil "GET / HTTP/1.0~%~%"))
 x)
 (force-output x)
 (let ((res (make-array 20
 :element-type
 '(unsigned-byte 8))))
 (values (read-sequence res x)
 (map 'string 'code-char res)))))
```

## socket-stream-ctx

## *Function*

Summary        Accesses the `SSL_CTX` attached to a socket stream.

Package        `comm`

Signature      `socket-stream-ctx socket-stream => ssl-ctx-pointer`

Arguments      `socket-stream`     A `socket-stream`.

Values          `ssl-ctx-pointer`    A foreign pointer of type `ssl-ctx-pointer`, or `nil`.

Description      The function `socket-stream-ctx` accesses the `SSL_CTX` that is attached to the `socket-stream` `socket-stream`.

It returns `nil` if SSL is not attached.

[ssl-pointer](#)

**ssl-cipher-pointer** *FLI type descriptor*

**Summary** An FLI type for use with SSL.

## Package comm

## Signature [ssl-cipher-pointer](#)

Description The FLI type **ssl-cipher-pointer** corresponds to the C type **SSL\_CIPHER\***.

**ssl-cipher-pointer-stack** *FLI type descriptor*

**Summary** An FLI type for use with SSL.

## Package comm

## Signature [ssl-cipher-pointer-stack](#)

Description The FLI type `ssl-cipher-pointer-stack` corresponds to the C type `STACK_OF(SSL_CIPHER)`.

**ssl-closed** *Class*

**Summary** The class for SSL errors corresponding to  
**SSL\_ERROR\_ZERO\_RETURN**.

## Package comm

## Superclasses    ***ssl-condition***

|             |                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Description | The condition class <code>ssl-closed</code> corresponds to <code>SSL_ERROR_ZERO_RETURN</code> . It means the underlying socket is dead. |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|

## **ssl-condition**

*Class*

Summary      The condition class for SSL errors.

Package      `comm`

Superclasses    `socket-error`

Subclasses    `ssl-closed`  
`ssl-error`  
`ssl-failure`  
`ssl-x509-lookup`

Description      The condition class for errors inside SSL.

## **ssl-ctx-pointer**

*FLI type descriptor*

Summary      An FLI type for use with SSL.

Package      `comm`

Signature     `ssl-ctx-pointer`

Description      The FLI type `ssl-ctx-pointer` corresponds to the C type `SSL_CTX*`.

## **ssl-error**

*Class*

Summary      The class for SSL errors corresponding to `SSL_ERROR_SYSCALL`.

|              |                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------|
| Package      | <code>comm</code>                                                                                                              |
| Superclasses | <code>ssl-condition</code>                                                                                                     |
| Description  | The condition class <code>ssl-error</code> corresponds to <code>SSL_ERROR_SYSCALL</code> . It means that something got broken. |

## **ssl-failure** *Class*

|              |                                                                                                                                                                                                                                                                                    |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary      | The class for SSL errors corresponding to <code>SSL_ERROR_SSL</code> .                                                                                                                                                                                                             |
| Package      | <code>comm</code>                                                                                                                                                                                                                                                                  |
| Superclasses | <code>ssl-condition</code>                                                                                                                                                                                                                                                         |
| Description  | The condition class <code>ssl-failure</code> corresponds to <code>SSL_ERROR_SSL</code> . This means a failure in processing the input, typically due to a mismatch between the client and the server. You get this error when trying to use a SSL connection to a non-secure peer. |

## **ssl-new** *Function*

|             |                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------|
| Summary     | Creates a <code>ssl</code> .                                                                                           |
| Package     | <code>comm</code>                                                                                                      |
| Signature   | <code>ssl-new ssl-ctx-pointer -&gt; ssl-pointer</code>                                                                 |
| Arguments   | <code>ssl-ctx-pointer</code> A foreign pointer of type <code>ssl-ctx-pointer</code> .                                  |
| Values      | <code>ssl-pointer</code> A foreign pointer of type <code>ssl-pointer</code> .                                          |
| Description | The function <code>ssl-new</code> creates a <code>ssl</code> by a direct call to the C function <code>SSL_new</code> . |

It returns a pointer to the new **SSL**.

**ssl-pointer**

## **ssl-pointer** *FLI type descriptor*

Summary      An FLI type for use with SSL.  
  
 Package      **comm**  
  
 Signature      **ssl-pointer**  
  
 Description      The FLI type **ssl-pointer** corresponds to the C type **SSL\***.

## **ssl-x509-lookup** *Class*

Summary      The class for SSL errors corresponding to  
**SSL\_ERROR\_WANT\_X509\_LOOKUP**.  
  
 Package      **comm**  
  
 Superclasses      **ssl-condition**  
  
 Description      The condition class **ssl-x509-lookup** corresponds to  
**SSL\_ERROR\_WANT\_X509\_LOOKUP**. It happens when a certificate is rejected by a user callback.

## **start-up-server** *Function*

Summary      Starts a TCP server.  
  
 Package      **comm**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                 |

|             | <i>startup-condition</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | A condition object, or <code>nil</code> .                                       |
| Description | <p>The function <code>start-up-server</code> starts a TCP server. Use <code>open-tcp-stream</code> to send messages from another client to the server.</p> <p>The <i>function</i> argument provides the name of the function that processes connections. When a connection is made <i>function</i> is called with the connected socket handle, at which point you can make a stream using <code>make-instance</code> and communicate with the client. The server does not accept more connections until <i>function</i> returns, so normally it should create another light-weight process to handle the connection. However, the operating system typically provides a small queue of partially accepted connections, which prevents connection failure for new clients until the server is ready to accept more connections. If <i>function</i> is not specified the built-in Lisp listener server is used. See the examples section below.</p> |                                                                                 |

If *announce* is a stream or `t` (denoting `*standard-output*`), a message appears on the stream when the server is started.

If *announce* is a function it is called when the server is started. *announce* should take two arguments: *socket* and *condition*. *socket* is the socket used by the server: *announce* can therefore be used to record this socket. *condition* describes the error if there is one. *announce* can be called with *socket nil* and a condition only if *error* is *nil*. If the process is killed, *announce* is called with *socket nil* and *condition nil*.

The default for *announce* is *nil*, meaning there is no message.

If *service* is a string or positive integer, it specifies the name of the service. The location of the file specifying the names of services available varies, but typically on Windows 98 it is called `SERVICES` and is stored in the `Windows` directory, and on Windows NT-based systems it is the file

```
%SystemRoot%\system32\drivers\etc\SERVICES
```

If *service* is *nil* or 0, then `start-up-server` chooses a free port. The default value for *service* is "lispworks".

If *address* is a string or an `ipv6-address` object or an integer that can be resolved to an IP address, then the server only receives connections for that IP address. This must be one of the addresses associated with the machine and allowed values are a string naming a host, such as "`www.nowhere.com`", a string providing the IP address, such as "`204.71.177.75`", or an integer IP address in network order, such as `#xCC47B14B`.

If *address* is *nil* or 0, then the server will receive connections to all IP addresses on the machine. This is the default.

*address* also determines which family is used when making the socket. `AF_INET6` is used in these cases:

- The address is an `ipv6-address`.
- The address is a string specifying an IPv6 address.

- The address is a string that resolves to an IPv6 address.

Otherwise `AF_INET` is used. When `address` is not supplied, `AF_INET` is used. To open a server with `AF_INET6` listening to any address, either use the keyword argument `ipv6` or pass the zero IPv6 address "`::`".

If `keepalive` is true, `SO_KEEPALIVE` is set on the socket. The default value of `keepalive` is `nil`.

If `nodelay` is true, `TCP_NODELAY` is set on the socket. The default value of `nodelay` is `t`.

The `process-name` specifies the process name. The default is constructed from the service name in the following fashion:

```
(format nil "~S server" service)
```

The `wait` argument controls whether `start-up-server` waits for the server to start or returns immediately. When `wait` is non-`nil` and an error was signalled, `process` is `nil` and the error is returned in `startup-condition`. Otherwise just one value, the server process, is returned. The default for `wait` is `nil`.

`ipv6` affects the resolution of `address` if it is a string or `nil`. When `ipv6` is `nil`, it forces IPv4 addresses, and if `ipv6` is `t` it forces IPv6 addresses. The value `:any` has no effect. The default value of `ipv6` is `:any`.

The `error` argument controls what happens if an error is signalled in the server thread. If `error` is `nil` then the thread is terminated. If `error` is non-`nil` then the debugger is entered. The default value for `error` is `(not wait)`.

**Notes** Some versions of Microsoft Windows fail to detect the case where more than one server binds a given port, so an error will not be raised in this situation.

**Examples** The following example uses the built-in Lisp listener server:

```
(comm:start-up-server :service 10243)
```

It makes a Lisp listener server on port 10243 (check with local network managers that this port number is safe to use). When a client connects to this, Lisp calls `read`. The client should send a string using Common Lisp syntax followed by a newline. This string is used to name a new light-weight process that runs a Lisp listener. When this has been created, the server waits for more connections.

The next example illustrates the use of the *function* argument. For each line of input read by the server it writes the line back with a message. The stream generates `EOF` if the other end closes the connection.

```
(defvar *talk-port* 10244) ; a free TCP port number

(defun make-stream-and-talk (handle)
 (let ((stream (make-instance 'comm:socket-stream
 :socket handle
 :direction :io
 :element-type
 'base-char)))
 (mp:process-run-function (format nil "talk ~D"
 handle)
 '()
 'talk-on-stream stream)))

(defun talk-on-stream (stream)
 (unwind-protect
 (loop for line = (read-line stream nil nil)
 while line
 do
 (format stream "You sent: '~A'~%" line)
 (force-output stream))
 (close stream)))

(comm:start-up-server :function 'make-stream-and-talk
 :service *talk-port*)
```

This is a client which uses the talk server:

```

(defun talking-to-myself ()
 (with-open-stream
 (talk (comm:open-tcp-stream "localhost"
 talk-port))
 (dolist (monolog
 '("Hello self."
 "Why don't you say something original?"
 "Talk to you later then. Bye."))
 (write-line monolog talk)
 (force-output talk)
 (format t "I said: \"~A\"~%" monolog)
 (format t "Self replied: \"~A\"~%" (read-line talk nil nil)))))

(talking-to-myself)
=>
I said: "Hello self."
Self replied: "You sent: 'Hello self.'"
I said: "Why don't you say something original?"
Self replied: "You sent: 'Why don't you say something
original?'"
I said: "Talk to you later then. Bye."
Self replied: "You sent: 'Talk to you later then.
Bye.'"

```

This example illustrates a server which picks a free port and records the socket. The last form queries the socket for the port used.

```

(defvar *my-socket* nil)

(defun my-announce-function (socket condition)
 (if socket
 (setf *my-socket* socket)
 (my-log-error condition)))

(comm:start-up-server :service nil
 :error nil
 :announce 'my-announce-function)

(multiple-value-bind (address port)
 (comm:get-socket-address *my-socket*)
 port)

```

| Arguments   | <i>ip-address-string</i> A string denoting an IP address in either dotted format for IPv4 or standard IPv6 format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                         |
| Values      | <i>ip-address</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Either an integer representing an IPv4 address, or an <code>ipv6-address</code> object. |
| Description | <p>The <code>string-ip-address</code> function takes a string in the standard dotted IP address notation <code>a.b.c.d</code> and returns the corresponding integer IP address.</p> <p>The function <code>string-ip-address</code> takes a string and tries to parse as an IP address. If <i>ip-address-string</i> is in a proper dotted IP address format, it returns an integer representing an IPv4 address. Otherwise it tries to read it as an IPv6 address using <code>parse-ipv6-address</code> (with <code>trim-whitespace-p nil</code>), which returns an <code>ipv6-address</code> object if it is successful or <code>nil</code> if it fails.</p> |                                                                                         |

| Arguments                  | <i>stream</i>                                                   | A stream created using <code>open-tcp-stream</code> . |
|                            | <i>body</i>                                                     | Code to be executed while the stream is “noticed”.    |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The macro <b>with-noticed-socket-stream</b> evaluates the <i>body</i> forms with the stream <i>stream</i> "noticed" for input. <i>stream</i> becomes unnoticed afterwards.</p> <p>The macro is designed to be used with streams created by <b>open-tcp-stream</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                       |
| Notes       | <ol style="list-style-type: none"><li>1. You do not normally need to use this macro, because all of the standard functions that read from socket streams (<b>read-char</b> and so on) will do this automatically when necessary. However, if you call <b>process-wait</b> yourself with a <i>wait-function</i> that detects new input from a socket stream, then this macro is necessary to cause LispWorks to evaluate the <i>wait-function</i> when there is input on the underlying socket. Without that, there might be a delay before the thread responds to the input.</li><li>2. <b>with-noticed-socket-stream</b> is not implemented on the Windows platform.</li></ol> |

## The COMMON-LISP Package

This chapter describes the LispWorks extensions to symbols in the **COMMON-LISP** package, which is used by default. This chapter notes only those differences between LispWorks and the ANSI Common Lisp standard. You should refer to this standard (an HTML version, the Common Lisp Hyperspec, is supplied with LispWorks) for full documentation about standard Common Lisp symbols.

| apropos   |                      |                                                                                                       |
| Summary   |                      | Searches for interned symbols.                                                                        |
| Package   |                      | <code>common-lisp</code>                                                                              |
| Signature |                      | <code>apropos <i>string</i> &amp;optional <i>package external-only</i> =&gt; &lt;no values&gt;</code> |
| Arguments | <i>string</i>        | A string designator.                                                                                  |
|           | <i>package</i>       | A package designator or <code>nil</code> .                                                            |
|           | <i>external-only</i> | A generalized boolean.                                                                                |

|             |                                                                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The function <code>apropos</code> behaves as specified in ANSI Common Lisp. There is an additional optional argument <code>external-only</code> , which if true restricts the search to symbols which are external in the searched package or packages. The default value of <code>external-only</code> is <code>nil</code> . |

| Description        | The standard function <code>close</code> is implemented as a generic function. All external resources used by the stream should be freed and true returned when that has been done. The result value for <code>close</code> is as per the Common Lisp ANSI specification.                                                                             |                                               |
|                    | When <code>stream</code> is an instance of a subclass of <code>buffered-stream</code> , if <code>abort</code> is true then any remaining data in the buffer can be discarded. There are two built-in methods on <code>buffered-stream</code> . The primary method specialized on <code>buffered-stream</code> returns t. The other, an :around method |                                               |

specialized on `buffered-stream`, flushes the stream buffer if `abort` is `nil`, calls the next method and marks the stream as closed if that method returns true. Thus the only requirement for a primary method specialized on a subclass of `buffered-stream` is that it must close any underlying data source and return true.

The `close` method on the `fundamental-stream` class sets a flag for `open-stream-p`

| Values             | <i>result</i> An object of type <i>result-type</i>                                                                                                                                                                                                                       |               |                |                    |                   |
| Description        | The <code>coerce</code> function still performs those conversions required by the standard, but a larger set of type specifiers is allowed for coercion. A <code>type-error</code> is signalled if <i>result</i> cannot be returned as the <i>result-type</i> specifies. |               |                |                    |                   |

| <i>name</i>       | A function name or <code>nil</code> or a list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |             |                                                |                   |                                    |
| <i>definition</i> | A lambda expression or a function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |             |                                                |                   |                                    |
| Description       | <p><code>compile</code> calls the compiler to translate a lambda expression into a code vector containing an equivalent sequence of host specific machine code. A compiled function typically runs between 10 and 100 times faster. It is generally worth compiling the most frequently called Lisp functions in a large application during the development phase. The compiler detects a large number of programming errors, and the resulting code runs sufficiently faster to justify the compilation time, even during development.</p> <p>Warning messages are printed to <code>*error-output*</code>. Other messages are printed to <code>*standard-output*</code>.</p> <p><i>definition</i> and the return values are as specified for Common Lisp. Note that <i>name</i> may be a list not of the form <code>(setf symbol)</code>, which is an extension to Common Lisp.</p> <p><code>compile</code> also supports a LispWorks-specific extension allowing <code>compile</code> to compile an arbitrary form. When <i>definition</i> is not supplied and <i>name</i> is a list not of the form <code>(setf symbol)</code>, <code>compile</code> compiles it as if by <code>compile-file</code> but without any file related processing and does it in-memory, so it has also the same effect as loading. This has a similar effect to compiling a definition in the LispWorks Editor tool, except that there is no source recording. Multiple forms can be compiled in one call by wrapping them with <code>progn</code>. When <code>compile</code> is used this way it always returns <code>nil</code>.</p> |             |                                                |                   |                                    |

|                    |                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes              | A compiled function object may be returned. Such compiled function objects are not printable (but see <code>disassemble</code> ) other than as #<Function FOO hex-address>.                                                                                                                                                               |
| Compatibility note | In LispWorks 5.1 and previous versions, warning messages are printed to <code>*standard-output*</code> .                                                                                                                                                                                                                                  |
| Examples           | <pre>(defun fn (...) ...) ; interpreted definition for fn (compile 'fn)          ; replace with compiled                       ; definition (compile nil '(lambda (x) (* x x)))                       ; returns compiled squaring function (compile 'cube '(lambda (x) (* x x x)))                       ; defun and compile in one</pre> |
| Notes              | See <code>declare</code> for a list of the declarations that alter the behavior of the compiler.                                                                                                                                                                                                                                          |

| Values      | <i>output-truename</i> | A pathname or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|             | <i>warnings-p</i>      | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | <i>failure-p</i>       | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description |                        | <p>The function <code>compile-file</code> calls the compiler to translate a Lisp source file into a form that both loads and runs faster. A compiled function typically runs more than ten times faster than when interpreted (assuming that it is not spending most of its work calling already compiled functions). A source file with a <code>.lisp</code> or <code>.lsp</code> extension compiles to produce a file with a <code>.*fasl</code> extension (the actual extension depends on the host machine CPU and the LispWorks implementation). Subsequent use of <code>load</code> loads the compiled version (which is in LispWorks's FASL or Fast Load format) in preference to the source.</p> <p>In compiling a file the compiler has to both compile each function and top level form in the file, and to produce the appropriate FASL directives so that loading has the desired effect. In particular objects need to have space allocated for them, and top level forms are called as they are loaded.</p> <p><i>output-file</i> specifies the location of the output file, relative to the current directory (not the path of the file). If it specifies a directory, then the output file is placed there instead of the same directory as the source. If it contains a file name but not a file type, then the platform specific file type is added and the result specifies the full path of the output file. If <i>output-file</i> has a type, it specifies the full path of the output file. Note that in this case when you want to load the file you will need to add the type to <code>*binary-file-types*</code>. See the example below.</p> |

The special value *output-file* :`temp` offers a convenient way to specify that the output file is a temporary file in a location that is likely to be writable.

*verbose* controls the printing of messages describing the file being compiled, the current optimization settings, and other information. If *verbose* is `nil`, there are no messages. If *verbose* is `0`, only the "Compiling file..." message is printed. For all other true values of *verbose*, messages are also printed about:

- compiler optimization settings before the file is processed, and
- multiple matches when *input-file* does not specify the pathname type, and
- any clean down (garbage collection) that occurs during the compilation.

The default value is the value of `*compile-verbose*`, which defaults to `t`.

*print* controls the printing of information about the compilation. It can have the following values. If *print* is `nil`, no information is printed. If *print* is a non-positive number, then only warnings are printed. If *print* is a positive number no greater than 1, or if *print* is any non-number object, then the information printed consists of all warning messages and one line of information per function that is compiled. If *print* is a number greater than 1, then full information is printed. The default value of *print* is the value of `*compile-print*`, which has the default value 1.

Warning messages are printed to `*error-output*`. Other messages are printed to `*standard-output*`.

*external-format* is interpreted as for `open`. The default value is `:default`.

If *load* is true, then the file is loaded after compilation.

*output-truename* is the `truename` of the output file, or `nil` if that cannot be created.

`warnings-p` is `nil` if no conditions of type `error` or `warning` were detected during compilation. Otherwise `warnings-p` is a list containing the conditions.

`failure-p` is `nil` if no conditions of type `error` or `warning` (other than `style-warning`) were detected by the compiler, and `t` otherwise.

Compatibility note In LispWorks 5.1 and previous versions, warning messages are printed to `*standard-output*`.

Examples

```
(compile-file "devel/fred.lisp")
 ;; compile fred.lisp to fred.fasl
(compile-file "devel/fred")
 ;; does the same thing

(compile-file "test" :load t)
 ;; compile test.lisp, then load if successful

(compile-file "program" :output-file "program.abc")
 ;; compile "program.lisp" to "program.abc"

(push "abc" sys:*binary-file-types*)
 ;; tells LispWorks that files with extension
 ;; ".abc" are binaries
```

Notes See `declare` for a list of the declarations that alter the behavior of the compiler.

The act of compiling a file should have no side effects, other than the creation of symbols and packages as the input file is read by the reader.

By default a form is skipped if an error occurs during compilation. If you need to debug an error during compilation by `compile-file`, set `*compiler-break-on-error*`.

During compilation of a file `foo.lisp` (on an Intel Macintosh, for example) a temporary output file named `t_foo.xfasl` is used, so that an unsuccessful compile does not overwrite an existing `foo.xfasl`.

LispWorks uses the following naming conventions for fasl files, and it is recommended that you should use them too, to ensure correct operation of `load` and so on.

Table 27.1 Naming conventions for FASL files

| Machine/Implementation             | Fasl Extension   |
|------------------------------------|------------------|
| x86 Windows/32-bit LispWorks       | . <b>ofasl</b>   |
| x64 Windows/64-bit LispWorks       | . <b>64fasl</b>  |
| x86 Linux/32-bit LispWorks         | . <b>ufasl</b>   |
| amd64 Linux/64-bit LispWorks       | . <b>64ufasl</b> |
| x86 FreeBSD/32-bit LispWorks       | . <b>ffasl</b>   |
| x86 FreeBSD/64-bit LispWorks       | . <b>64ffasl</b> |
| HP-PA/32-bit LispWorks             | . <b>pfasl</b>   |
| SPARC/32-bit LispWorks             | . <b>wfasl</b>   |
| SPARC/64-bit LispWorks             | . <b>64wfasl</b> |
| x86 Solaris/32-bit LispWorks       | . <b>sfasl</b>   |
| amd64 Solaris/64-bit LispWorks     | . <b>64sfasl</b> |
| Intel Macintosh/32-bit LispWorks   | . <b>xfasl</b>   |
| PowerPC Macintosh/32-bit LispWorks | . <b>nfasl</b>   |
| Intel Macintosh/64-bit LispWorks   | . <b>64xfasl</b> |
| PowerPC Macintosh/64-bit LispWorks | . <b>64nfasl</b> |

You can find the fasl file extension appropriate for your machine by looking at the variable `*binary-file-type*`. The variable `*binary-file-types*` contains a list of all the file extensions currently recognized by `load`, `require` and `load-data-file` (in addition to `*binary-file-type*`).

|                    |                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| Compatibility Note | In LispWorks for Windows 4.4 and previous, the fasl file extension is <code>.fasl</code> . This changed in LispWorks 5.0.         |
|                    | In LispWorks for Linux 4.4 and previous, the fasl file extension is <code>.ufasl</code> . This changed in LispWorks 5.0.          |

## concatenate *Function*

|             |                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Extends the standard <code>concatenate</code> function allowing it to take any Common Lisp type.                                                                                                                                                   |
| Package     | <code>common-lisp</code>                                                                                                                                                                                                                           |
| Signature   | <code>concatenate result-type &amp;rest sequences =&gt; result-sequence</code>                                                                                                                                                                     |
| Arguments   | <code>result-type</code> A type specifier.<br><code>sequences</code> A sequence.                                                                                                                                                                   |
| Values      | <code>result-sequence</code> A sequence.                                                                                                                                                                                                           |
| Description | The <code>concatenate</code> function has been extended to take any Common Lisp type. The <code>result-sequence</code> will be of type <code>result-type</code> unless this is not possible, in which case a <code>type-error</code> is signalled. |

| Arguments   | <i>declarations</i> Declaration forms.                                                                                                                                                                                                                                                                                  |
| Description | The macro <code>declare</code> behaves as specified in the ANSI Common Lisp Standard with one exception: for a top-level call to <code>declare</code> , optimize declarations are omitted from the compiled binary file. This is useful because you are unlikely to want to change these settings outside of that file. |

| Summary        | Declares a variable as special, provides advice to the Common Lisp system, or helps the programmer to optimize code.                                                                                                                                                                                                                                                                                                 |
| Package        | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                             |
| Signature      | <code>declare declaration*</code>                                                                                                                                                                                                                                                                                                                                                                                    |
| Arguments      | <i>declaration</i> A declaration specifier, not evaluated.                                                                                                                                                                                                                                                                                                                                                           |
| Values         | The special form <code>declare</code> behaves computationally as if it is not present (other than to affect the semantics), and is only allowed in certain contexts, such as after the variable list in a <code>let</code> , <code>do</code> , <code>defun</code> and so on.<br><br>(Consult the syntax definition of each special form to see if it takes <code>declare</code> forms and/or documentation strings.) |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>There are three distinct uses of <code>declare</code>: one is to declare Lisp variables as “special” (this affects the semantics of the appropriate bindings of the variables), the second is to provide advice to help the Common Lisp system (in reality the compiler) run your Lisp code faster or with more sophisticated debugging options, and the third (using the <code>:explain</code> declaration) is to help you optimize your code.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|             | <p>If you use <code>declare</code> to specify types (and so eliminate type-checking for the specified symbols) and then supply the wrong type, you may obtain a “Segmentation Violation”. You can check this by interpreting the code (rather than compiling it).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|             | <p>The following are extensions to the Common Lisp definition of <code>declare</code>:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|             | <ul style="list-style-type: none"> <li>• <code>hcl:special-global</code> declares that the symbol is never bound.<br/>           In SMP LispWorks the compiler signals error if it detects that a symbol declared as <code>hcl:special-global</code> is bound, and at runtime it also signals an error.<br/>           In non-SMP LispWorks the compiler gives an error, but there is no runtime check. The runtime behavior is the same as <code>cl:special</code>, with all accesses to the symbol in low safety.<br/> <code>hcl:special-global</code> is very useful, and because of the checks it is reasonably safe. It is useful not only for speed, but also to guard against unintentionally binding variables that should not be bound.<br/>           See also <code>defglobal-parameter</code>.         </li> <li>• <code>hcl:special-dynamic</code> declares that the symbol is never accessed outside the dynamic scope of the binding.<br/>           In high safety code accessing the symbol outside the scope of binding signals an error. In low safety code it may result in unpredictable behavior.</li> </ul> |

In non-SMP LispWorks the only effect of this declaration is to make all access to the variable low safety.

`hcl:special-dynamic` is useful, but because it can lead to unpredictable behavior you need to ensure that you test your program in high safety when you use it.

- `hcl:special-fast-access` declares that a symbol should be "fast access".

The semantics of the declaration is the same as `cl:special`, except that access to the variable is low safety. In addition, the compiler compiles access to the symbol in a way that speeds up the access, but also introduces a tiny reduction in the speed of the whole system. The balance between these effects is not obvious.

It is not obvious where `hcl:special-fast-access` is useful. If you can ensure that the symbol is always bound or never bound then `hcl:special-dynamic` or `hcl:special-global` are certainly better.

- `hcl:lambda-list` specifies the value to be returned when a programmer asks for the arglist of a function.
- `values` specifies the value to be returned when you ask for a description of the results of a function.
- `hcl:invisible-frame` specifies that calls to this function should not appear in a debugger backtrace.
- `hcl:alias` specifies that calls to this function should be displayed as calls to an alternative function in a debugger backtrace.
- `:explain` controls messages printed by the compiler while it is processing forms.

The remainder of this description documents the syntax and use of `:explain` declarations.

`declaration ::= (:explain option*)`

`option ::= optionkey | (optionkey optionvalue)`

```
optionkey ::= :none | :variables | :types | :floats |
:non-floats | :all-calls | :all-calls-with-arg-types |
:calls | :boxing | :print-original-form | :print-
expanded-form | :print-length | :print-level
```

The `:explain` declaration controls messages printed by the compiler while it is processing forms. The declaration can be used with `proclaim` or `declare` as a top level form to give it global or file scope. It can also be used at the start of a `#'lambda` form or function body to give it the scope of that function. The declaration has unspecified effect when used in other contexts, for example in the body of a `let` form.

An `:explain` declaration consists of a set of options of the form (*optionkey optionvalue*) which associates *optionvalue* with *optionkey* or *optionkey* which associates `t` with *optionkey*. By default, all of the *optionkeys* have an associated value `nil`. All *optionkeys* not specified by a declaration remain unchanged (except for the special action of the `:none` *optionkey* described below).

The *optionkey* should be one of the following:

- |                          |                                                                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>:none</code>       | Set value associated with all <i>optionkeys</i> to <code>nil</code> . This turns off all explanations.                                                 |
| <code>:variables</code>  | If <i>optionvalue</i> is non- <code>nil</code> , list all the variables of each function, specifying whether they are floating point or not.           |
| <code>:types</code>      | If <i>optionvalue</i> is non- <code>nil</code> , print information about compiler transformations that depend on declared or deduced type information. |
| <code>:floats</code>     | If <i>optionvalue</i> is non- <code>nil</code> , print information about calls to functions that may allocate floats.                                  |
| <code>:non-floats</code> | If <i>optionvalue</i> is non- <code>nil</code> , print information about calls to functions that may allocate non-float numbers, for example bignums.  |

|                                  |                                                                                                                                                                                             |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>:all-calls</b>                | If <i>optionvalue</i> is non-nil, print information about calls to normal functions.                                                                                                        |
| <b>:all-calls-with-arg-types</b> | If <i>optionvalue</i> is non-nil, print the argument types for calls to normal functions. Must be combined with <b>:all-calls</b> .                                                         |
| <b>:calls</b>                    | A synonym for <b>:all-calls</b> .                                                                                                                                                           |
| <b>:boxing</b>                   | If <i>optionvalue</i> is non-nil, print information about calls to functions that may allocate numbers, for example floats or bignums.                                                      |
| <b>:print-original-form</b>      | If <i>optionvalue</i> is non-nil, modifies the <b>:all-calls</b> , <b>:floats</b> and <b>:non-floats</b> explanations to include the original source code form that contains the call.      |
| <b>:print-expanded-form</b>      | If <i>optionvalue</i> is non-nil, modifies the <b>:all-calls</b> , <b>:floats</b> and <b>:non-floats</b> explanations to include the macroexpanded source code form that contains the call. |
| <b>:print-length</b>             | Use the <i>optionvalue</i> as the value of <b>*print-length*</b> for <b>:all-calls</b> , <b>:floats</b> and <b>:non-floats</b> explanations.                                                |
| <b>:print-level</b>              | Use the <i>optionvalue</i> as the value of <b>*print-level*</b> for <b>:all-calls</b> , <b>:floats</b> and <b>:non-floats</b> explanations.                                                 |

|          |                                                                                                                                                                                                                                                                                                                                                                                |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example  | <pre>(defun foo (arg)   (declare     (:explain :variables)     (:optimize (float 0)))   (let* ((double-arg (coerce arg 'double-float))          (next (+ double-arg 1d0))          (other (* double-arg 1/2)))     (values next other)))   ;;- Variables with non-floating point types:   ;;- ARG OTHER   ;;- Variables with floating point types:   ;;- DOUBLE-ARG NEXT</pre> |

## **defclass** *Macro*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Remains as defined in ANSI Common Lisp, but extra control over parsing of class options and slot options, optimization of slot access, and checking of initargs, is provided.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Package     | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description | <p>The macro <code>defclass</code> is as defined in the ANSI standard with the following extensions.</p> <p>For extra class options, you may need to define the way these are parsed at <code>defclass</code> macroexpansion time. See <code>process-a-class-option</code> for details.</p> <p>For non-standard slot options, you may need to define the way these are parsed at <code>defclass</code> macroexpansion time. See <code>process-a-slot-option</code> for details.</p> <p>By default, standard slot accessors are optimized such that they do not call <code>slot-value-using-class</code>. This optimization can be switched off using the <code>:optimize-slot-access nil</code> class option.</p> |

To add valid initialization arguments for the class, use the class option `:extra-initargs`. The argument passed via this option is evaluated, and should return a list of extra initialization arguments for the class. `make-instance` and other CLOS initializations (see `set-clos-initarg-checking`) will treat these as valid when checking their arguments.

- |               |                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Compatibility | When a class is redefined, its extra initargs are always reset.                                                                                                                                        |
| Note          | In early versions of LispWorks 4.3, extra initargs were not reset when a class was redefined without specifying extra initargs.                                                                        |
| Example       | This session illustrates the effects of the <code>:optimize-slot-access</code> class option. When true, slot access is more efficient but note that <code>slot-value-using-class</code> is not called. |

```

CL-USER 26 > (compile '(defclass foo ()
 ((a :type fixnum
 :initarg :a
 :reader foo-a))))
NIL

CL-USER 27 > (compile '(defclass bar ()
 ((a :type fixnum
 :initarg :a
 :reader bar-a))
 (:optimize-slot-access nil)))
NIL

CL-USER 28 > (setf *foo*
 (make-instance 'foo :a 42)
 bar (make-instance 'bar :a 99))
#<BAR 21D33D4C>

CL-USER 29 > (progn
 (time (dotimes (i 1000000)
 (foo-a *foo*)))
 (time (dotimes (i 1000000)
 (bar-a *bar*))))
Timing the evaluation of (DOTIMES (I 1000000) (FOO-A
FOO))

user time = 0.328
system time = 0.015
Elapsed time = 0:00:00
Allocation = 2280 bytes standard / 11002882 bytes

 << VALUE-0 : 99
99
```

This session illustrates the `:extra-initargs` class option:

```

CL-USER 46 > (defclass a () ())
 (:extra-initargs '(:a-initarg)))
#<STANDARD-CLASS A 21C2E4FC>

CL-USER 47 > (defclass b (a) ())
 (:extra-initargs '(:b-initarg)))
#<STANDARD-CLASS B 2068573C>

CL-USER 48 > (defclass c (a) ())
#<STANDARD-CLASS C 22829D44>

CL-USER 49 > (make-instance 'b :a-initarg "A" :b-
initarg "B")
#<B 2068BCE4>

CL-USER 50 > (make-instance 'c :a-initarg "A" :b-
initarg "B")

Error: MAKE-INSTANCE is called with unknown keyword :B-
INITARG among the arguments (C :A-INITARG "A" :B-
INITARG "B") which is not one of (:A-INITARG).
 1 (continue) Ignore the keyword :B-INITARG
 2 (abort) Return to level 0.
 3 Return to top loop level 0.

Type :b for backtrace, :c <option number> to proceed,
or :? for other options

CL-USER 51 : 1 >

|             | <i>add-use-defaults</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | A keyword            |
| Values      | <i>package</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | A package.           |
| Description | <p>The macro <code>defpackage</code> is as defined in the ANSI standard, with the inclusion of the <code>:add-use-defaults</code> keyword. However, the standard explicitly declines to define what <code>defpackage</code> does if a package named <i>defined-package-name</i> already exists and is in a state that differs from that described by the <code>defpackage</code> form.</p> <p>Therefore an extension has been written that allows you to select between alternative behaviors. See <code>*handle-existing-defpackage*</code> for full details.</p> <p>One non-standard <i>option</i> is supported. <code>:add-use-defaults</code>, with a true argument, causes the package <i>defined-package-name</i> to inherit from the following packages (as well as any explicitly specified by the <code>:use</code> option):</p> <ul style="list-style-type: none"> <li>• <code>common-lisp</code></li> <li>• <code>lispworks</code></li> <li>• <code>harlequin-common-lisp</code></li> </ul> |                      |
| Example     | <pre>(defpackage "MY-PACKAGE" (:use "CAPI")            (:add-use-defaults t))  (package-use-list "MY-PACKAGE") =&gt; (#&lt;PACKAGE COMMON-LISP&gt; #&lt;PACKAGE LISPWORKS&gt; #&lt;PACKAGE HARLEQUIN-COMMON-LISP&gt; #&lt;PACKAGE CAPI&gt;)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                      |

|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>test</i>                           | Filtering test (only pathnames matching the test are collected).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>directories</i>                    | A boolean controlling whether non-matching directories are included in the result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>flat-file-namestring</i>           | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>link-transparency</i>              | If <code>nil</code> , then symbolic links are not followed. This means that returned names are not necessarily truenames, but has the useful feature that the <code>pathname-directory</code> of each pathname returned is the directory supplied as argument.<br><br>The default value of <i>link-transparency</i> is given by the special variable, <code>*directory-link-transparency*</code> , which has initial value <code>t</code> on UNIX/Linux/Mac OS X. By setting this variable to <code>nil</code> , you can get the old behavior of <code>directory</code> . On Windows, where the file system does not normally support symbolic links, this variable is initially <code>nil</code> . |
| <i>non-existent-link-destinations</i> | If this is non-nil, then the pathname pointed to by a symbolic link appears in the output whether or not this file actually exists. If <code>:link-transparency</code> is non-nil and <code>:non-existent-link-destinations</code> is <code>nil</code> (this is the default on UNIX/Linux/Mac OS X), then symbolic links to nonexistent files do not appear.<br><br>The default value is <code>nil</code> .                                                                                                                                                                                                                                                                                         |
| Values                                | <i>pathnames</i><br>A list of physical pathnames.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p><code>directory</code> collects all the pathnames matching the given pathname.</p> <p><code>directory</code> returns truenames, conforming to the ANSI specification for Common Lisp. Some programs may depend on the old behavior, however (and <code>directory</code> is slower if it has to find the truename for every file in the directory), and so two keyword arguments are available so that the old behavior can still be used: <i>link-transparency</i> and <i>non-existent-link-destinations</i>.</p> <p>Because truenames are now returned, the entries <code>.</code> and <code>..</code> no longer show up in the output of <code>directory</code>. This means, for instance, that</p> <pre>(directory #P"/usr/users/")</pre> <p>does not include <code>#P"/usr"</code>, which is the truename of <code>#P"/usr/users/.."</code></p> <p>The specification is unclear as to the appropriate behavior of <code>directory</code> in the presence of links to non-existent files or directories. For example, if the directory contains <code>foo</code>, which is a symbolic link to <code>bar</code>, and there is no file named <code>bar</code>, should <code>bar</code> show up in the directory listing? A keyword argument has been added which lets you control this behavior.</p> <p><code>directory</code> returns a single pathname if called with a non-wild (fully-specified) <i>pathname</i>. LispWorks <i>truenames</i> are fully-specified, so this affects recursive calls to <code>directory</code>.</p> <p><code>directories</code>, if non-nil, causes paths of directories that are sub-directories of the directory of the argument <i>pathname</i> to be included in the result, even if they do not match <i>pathname</i> in the name, type or version components. The default value of <code>directories</code> is <code>nil</code>.</p> <p>When <code>flat-file-namestring</code> is non-nil, <code>directory</code> matches the <code>file-namestring</code> of <i>pathname</i> as a flat string, rather than a</p> |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

pathname name and pathname type. The default value of *flat-file-namestring* is `nil`.

**Note:** The Search files tool in the LispWorks IDE uses this option when the **Match flat file-namestring** option is selected. See the *LispWorks IDE User Guide* for more information about the Search Files tool.

**Note:** File names containing the character `*` cannot be handled by LispWorks. This is because LispWorks uses `*` as a wildcard, so there can be confusion if a file name containing `*` is created, for example in the *pathnames* returned by `directory`.

Compatibility Note The `:check-for-subs` argument, implemented in LispWorks 4.0.1 and previous versions, has been removed. This argument controlled whether directories in the result have null name components. This option is no longer valid since ANSI Common Lisp specifies that `directory` returns true-names.

Example `CL-USER 1 > (pprint (directory ".."))`

```
(#P"C:/Program Files/LispWorks/readme-6-1.txt"
 #P"C:/Program Files/LispWorks/lispworks-6-1-0-x86-
win32.exe"
 #P"C:/Program Files/LispWorks/license-6-1.txt"
 #P"C:/Program Files/LispWorks/lib/")
```

This session illustrates the effect of the *directories* argument:

```

CL-USER 5 > (pprint (directory "/tmp/t*"))

(#P"/tmp/test.lisp" #P"/tmp/test2/" #P"/tmp/test1/")

CL-USER 6 > (pprint (directory "/tmp/t*" :directories
t))

(#P"/tmp/patches/"
 #P"/tmp/test.lisp"
 #P"/tmp/test2/"
 #P"/tmp/opengl/"
 #P"/tmp/test1/"
 #P"/tmp/mnt/")

```

This example illustrates directory returning a single pathname in its result when given a full-specified pathname:

```

CL-USER 1 > (directory
 (make-pathname :host "H"
 :device :unspecific
 :directory (list :absolute
 "tmp")
 :name :unspecific
 :type :unspecific
 :version :unspecific))
 (#P"H:/tmp/")

```

The next two examples illustrate the effect of *flat-file-namestring*. Suppose the directory *dir* contains files *interp.exe* and *file.lisp*.

This call matches *interp.exe*, where the name *interp* ends with *p*, but does not match *file.lisp*, where the name *file* ends with *e*:

```
(directory "dir/*p")
```

The next call matches *file.lisp*, where the namestring *file.lisp* ends with *p*, but does not match *interp.exe*, where the namestring *interp.exe* ends with *e*:

```
(directory "dir/*p" :flat-file-namestring t)
```

| Summary            | Prints the machine code of a compiled function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Package            | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Signature          | <code>disassemble name-or-function =&gt; nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Arguments          | <code>name-or-function</code> Either a function object, a lambda expression or a symbol with a function definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description        | <p>This function prints the machine code of a compiled function, to <code>*standard-output*</code>.</p> <p>On UNIX and Mac OS X, the number of instructions in the disassembly is also printed, at the end.</p> <p>If the function denoted by <code>name-or-function</code> is not compiled then it is first compiled using the function <code>compile</code>. This happens if <code>name-or-function</code> is a lambda expression or a symbol naming an interpreted function.</p> <p>An error is signalled if <code>name-or-function</code> is not suitable.</p> |
| Examples           | <pre>(disassemble #'(lambda (x) (progn x))) (disassemble 'cons) (disassemble #'map)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Notes              | The output from <code>disassemble</code> lacks useful information such as local and lexical variable names and symbol names. The representation of integers or characters or Lisp objects in general is not easily readable without detailed knowledge of the internals of the Lisp system and the host machine instruction set.                                                                                                                                                                                                                                   |

| Summary     | Returns the documentation string if available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Package     | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Signature   | <code>documentation x doc-type =&gt; documentation</code><br><code>(setf documentation) new-value x doc-type =&gt; new-value</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description | The generic function <code>documentation</code> operates as specified in the ANSI Common Lisp standard. Additional methods with signatures:<br><br><code>documentation (dspec t) (doc-type (eql 'dspec:dspec))</code><br><code>(setf documentation) new-value (dspec t) (doc-type (eql 'dspec:dspec))</code><br>are provided.<br><br>This method allows finding or setting the documentation string when you know the <code>dspec</code> . See Chapter 7, “Dspecs: Tools for Handling Definitions” for information about <code>dspecs</code> .<br><br><code>dspec</code> must be a <code>dspec</code> , but it can be non-canonical. This method canonicalizes <code>dspec</code> and then calls <code>documentation</code> with the name as the first argument and the appropriate <code>dspec</code> class name as the second, thereby calling a standard <code>documentation</code> method.<br><br>If you define your own type of definitions ( <code>def-saved-value</code> for example) with <code>define-dspec-class</code> you can add methods on <code>documentation</code> for your <code>dspec</code> class:<br><br><code>(documentation (dspec t) (doc-type (eql 'def-saved-value)))</code><br>This allows LispWorks IDE commands such as <b>Expression &gt; Documentation</b> to display the documentation. |

|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary            | A subtype of <code>float</code> .                                                                                                                                                                                                                                                                |
| Package            | <code>common-lisp</code>                                                                                                                                                                                                                                                                         |
| Signature          | <code>double-float</code>                                                                                                                                                                                                                                                                        |
| Description        | <code>double-float</code> is disjoint from <code>short-float</code> and <code>single-float</code> in all LispWorks implementations in version 5.0 and later.                                                                                                                                     |
| Compatibility Note | In LispWorks 4.4 and previous on Windows and Linux platforms, all floats are of type <code>double-float</code> . However, there are distinct specialized array types ( <code>(array single-float)</code> , with single precision, and <code>(array double-float)</code> , with double precision. |

| Summary           | The features list.                                                                                                                           |
| Package           | <code>common-lisp</code>                                                                                                                     |
| Initial Value     | A list containing <code>:lispworks</code> . The actual value varies depending on the platform.                                               |
| Description       | The following features can be used to distinguish between platforms, or characteristics of the platform or of the Lisp-Works implementation. |
|                   | <code>:solaris2</code> Solaris2                                                                                                              |

|                              |                                                                                                                                                                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>:hp-ux</b>                | HP-UX                                                                                                                                                                                                                                  |
| <b>:svr4</b>                 | System 5 Release 4 machine (for example Solaris2)                                                                                                                                                                                      |
| <b>:linux</b>                | Linux                                                                                                                                                                                                                                  |
| <b>:darwin</b>               | The variant of FreeBSD underlying Mac OS X.                                                                                                                                                                                            |
| <b>:unix</b>                 | Unix, including all of the above.                                                                                                                                                                                                      |
| <b>:mswindows</b>            | Microsoft Windows, including 32-bit and 64-bit.                                                                                                                                                                                        |
| <b>:lispworks-64bit</b>      | 64-bit LispWorks.                                                                                                                                                                                                                      |
| <b>:lispworks-32bit</b>      | 32-bit LispWorks.                                                                                                                                                                                                                      |
| <b>:x86</b>                  | All images that run on the x86 architecture have this feature. This includes Intel Macintosh, FreeBSD, Linux (32-bit), x86/x64 Solaris (32-bit) and Windows (32-bit).<br><br><b>Note:</b> 64-bit LispWorks does not have this feature. |
| <b>:amd64, :x86-64, :x64</b> | Images that run on the amd64/x86_64/x64 architecture have each of these feautures. This includes Linux (64-bit), FreeBSD (64-bit), x86/x64 Solaris (64-bit) and Windows (64-bit).                                                      |
| <b>:sparc</b>                | Images that run on SPARC architecture.                                                                                                                                                                                                 |
| <b>:powerpc</b>              | Images that run on PowerPC architecture.                                                                                                                                                                                               |
| <b>:hppa</b>                 | Images that run in HP PA-RISC architecture.                                                                                                                                                                                            |
| <b>:little-endian</b>        | The compiler targets a little endian machine, for instance x86.                                                                                                                                                                        |

Code can distinguish the fifteen current LispWorks implementations like this:

```
#+(and :mswindows :lispworks-32bit)
"LispWorks (32-bit) for Windows"
#+(and :mswindows :lispworks-64bit)
"LispWorks (64-bit) for Windows"
#+(and :linux :lispworks-32bit)
"LispWorks (32-bit) for Linux"
#+(and :linux :lispworks-64bit)
"LispWorks (64-bit) for Linux"
#+(and freebsd :lispworks-32bit)
"LispWorks (32-bit) for FreeBSD"
#+(and freebsd :lispworks-64bit)
"LispWorks (64-bit) for FreeBSD"
#+(and :darwin :x86)
"LispWorks (32-bit) for Macintosh (running on Intel)"
#+(and :darwin :powerpc :lispworks-32bit)
"LispWorks (32-bit) for Macintosh (running on PowerPC)"
#+(and :darwin :x86-64 :lispworks-64bit)
"LispWorks (64-bit) for Macintosh (running on Intel)"
#+(and :darwin :powerpc :lispworks-64bit)
"LispWorks (64-bit) for Macintosh (running on PowerPC)"
#+(and :solaris2 :x86)
"LispWorks (32-bit) for Intel/Solaris"
#+(and :solaris2 :x86-64)
"LispWorks (64-bit) for Intel/Solaris"
#+(and :sparc :lispworks-32bit)
"LispWorks (32-bit) for Solaris"
#+(and :sparc :lispworks-64bit)
"LispWorks (64-bit) for Solaris"
#:hppa
"LispWorks for HP PA"
```

The following features can be used to distinguish between versions of LispWorks:

- :lispworks4 All major version 4 releases.
- :lispworks4.4 Release 4.4.x
- :lispworks5 All major version 5 releases.
- :lispworks5.0 Release 5.0.x
- :lispworks5.1 Release 5.1.x
- :lispworks6.0 Release 6.0.x

## **:lispworks6.1** Release 6.1.x

Every LispWorks 5 and LispWorks 6 image has exactly one of the features **:lispworks-32bit** and **:lispworks-64bit**.

The two LispWorks architectures, 32-bit and 64-bit, can be distinguished by the features **:lispworks-32bit** or **:lispworks-64bit**.

The following features are present in LispWorks with the meanings defined for ANSI CL:

```
:ansi-cl
:common-lisp
:ieee-floating-point
```

Note that sometimes it is necessary to write code that examines **\*features\*** at load time or run time. For example this is true when you put platform-dependent code in fasl files that are shared between multiple platforms.

For a LispWorks image with the CAPI loaded, **:capi** will appear on **\*features\***.

|       |                                                                                                                                                                                                                                                                                                                      |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes | LispWorks for Macintosh supports the native Mac OS X Cocoa-based GUI and the X11/GTK+ GUI. If you need to test for which of these libraries is loaded, check for the features <b>:cocoa</b> and <b>:gtk</b> . The X11/Motif GUI is also available by evaluating ( <b>(require "capi-motif")</b> ) in the GTK+ image. |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Arguments   | <i>stream</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | A stream.              |
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | A generalized boolean. |
| Description | <p>The predicate <code>input-stream-p</code> is implemented as a generic function. The default method returns <code>t</code> if <i>stream</i> is an input stream. If the user wants to implement a stream with no inherent directionality (and thus does not include <code>fundamental-input-stream</code> or <code>fundamental-output-stream</code>) but for which the directionality depends on the instance, then a method should be provided for <code>input-stream-p</code>.</p> <p>There is an example in “Stream directionality” on page 276.</p> |                        |
| See also    | <code>fundamental-input-stream</code><br><code>output-stream-p</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                        |

|             |                                                                                                                                                                                                 | <i>Function</i>        |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Summary     | A generic function that determines if an object is an interactive stream.                                                                                                                       |                        |
| Package     | <code>c1</code>                                                                                                                                                                                 |                        |
| Signature   | <code>interactive-stream-p <i>stream</i> -&gt; <i>bool</i></code>                                                                                                                               |                        |
| Arguments   | <i>stream</i>                                                                                                                                                                                   | A stream.              |
| Values      | <i>bool</i>                                                                                                                                                                                     | A generalized boolean. |
| Description | <p>The predicate <code>interactive-stream-p</code> is implemented as a generic function. The <code>fundamental-stream</code> class provides a default method that returns <code>nil</code>.</p> |                        |
| See also    | <code>input-stream-p</code><br><code>output-stream-p</code>                                                                                                                                     |                        |

|             |                          | <i>Function</i>                                                                                                                                                |
|-------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     |                          | Searches for and loads the definition of a logical host, if not already defined.                                                                               |
| Package     |                          | <code>cl</code>                                                                                                                                                |
| Signature   |                          | <code>load-logical-pathname-translations host =&gt; just-loaded</code>                                                                                         |
| Arguments   | <code>host</code>        | A logical host, expressed as a string.                                                                                                                         |
| Values      | <code>just-loaded</code> | A generalized boolean                                                                                                                                          |
| Description |                          | This function loads the translations for <code>host</code> by loading the file <code>host.lisp</code> from the LispWorks directory <code>translations</code> . |
| Example     |                          | <code>(load-logical-pathname-translations "EDITOR-SRC")</code>                                                                                                 |

|             |  | <i>Type</i>                                                                                                    |
|-------------|--|----------------------------------------------------------------------------------------------------------------|
| Summary     |  | A subtype of <code>float</code> .                                                                              |
| Package     |  | <code>common-lisp</code>                                                                                       |
| Signature   |  | <code>long-float</code>                                                                                        |
| Description |  | <code>long-float</code> is the same type as <code>double-float</code> in LispWorks, on all platforms.          |
| See also    |  | <code>double-float</code><br><code>parse-float</code><br><code>short-float</code><br><code>single-float</code> |

|             | <b>long-site-name</b>                                                                                                                                                                                             | <i>Function</i>                |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| Summary     | Identifies the physical location of the computer.                                                                                                                                                                 |                                |
| Package     | <code>common-lisp</code>                                                                                                                                                                                          |                                |
| Signature   | <code>long-site-name =&gt; description</code><br><code>(setf long-site-name) description =&gt; description</code>                                                                                                 |                                |
| Arguments   | <code>description</code>                                                                                                                                                                                          | A string or <code>nil</code> . |
| Description | The function <code>long-site-name</code> returns a string identifying the physical location of the computer. This should be set using <code>(setf long-site-name)</code> when you configure your LispWorks image. |                                |
| See also    | <code>short-site-name</code>                                                                                                                                                                                      |                                |
|             | <b>loop</b>                                                                                                                                                                                                       | <i>Macro</i>                   |
| Summary     | A macro that performs iteration.                                                                                                                                                                                  |                                |
| Package     | <code>c1</code>                                                                                                                                                                                                   |                                |
| Signature   | <code>loop {for as} var [type-spec]</code><br><code>    being {the each}{records record}</code><br><code>    {in of} query-expression =&gt; result</code>                                                         |                                |
| Arguments   | <code>var</code>                                                                                                                                                                                                  | A variable.                    |
|             | <code>query-expression</code> A SQL query-statement                                                                                                                                                               |                                |
| Values      | <code>result</code>                                                                                                                                                                                               | An object.                     |
| Description | The Common Lisp <code>loop</code> macro has been extended with a clause for iterating over query results. This extension is available only when the SQL interface has been loaded. See Chap-                      |                                |

ter 38, “The SQL Package”. For a full description of the rest of the Common Lisp `loop` facility, see the Common Lisp Hyperspec.

Each iteration of the loop assigns the next record of the table to the variable `var`. The record is represented in Lisp as a list. Destructuring can be used in `var` to bind variables to specific attributes of the records resulting from *query-expression*. In conjunction with the panoply of existing clauses available from the `loop` macro, the new iteration clause provides an integrated report generation facility.

- Example** This extended `loop` example, on each record returned as a result of the query, binds `name`, finds the salary (if any) from an associated hash-table, and for salaries greater than 20000: increments a count, accumulates the salary, and prints the details. Finally, the average salary is printed.

```
(loop
 for (name) being each record in
 [select [ename] :from [emp]]
 as salary = (gethash name *salary-table*)
 initially (format t "~&~20A~10D" 'name 'salary)
 when (and salary (> salary 20000))
 count salary into salaries
 and sum salary into total
 and do (format t "~&~20A~10D" name salary)
 else
 do (format t "~&~20A~10A" name "N/A")
 finally
 (format t "~2&Av Salary: ~10D" (/ total salaries)))
```

| Description       |                            | <p>The standard definition of <code>make-array</code> is extended to accept the keyword arguments <code>:weak</code>, <code>:allocation</code> and <code>:single-thread</code>.</p> <p>If <code>weak</code> is non-nil, then <code>displaced-to</code> must be <code>nil</code> and if <code>element-type</code> is supplied it must have <code>upgraded-array-element-type t</code>, otherwise an error is signalled. That is, you cannot make a weak array which is displaced or has <code>array-element-type</code> other than <code>t</code>. When <code>weak</code> is non-nil, it makes <code>new-array</code> weak.</p> <p>If <code>weak</code> is <code>nil</code>, then <code>make-array</code> behaves in the standard way, and <code>new-array</code> is not weak. The value <code>weak</code> defaults to <code>nil</code>.</p> <p>See <code>set-array-weak</code> for a description of weak arrays.</p> <p>The possible values for <code>allocation</code> have the following meanings:</p> <ul style="list-style-type: none"> <li><code>:new</code> Allocate the array normally.</li> <li><code>nil</code> Same meaning as <code>:new</code>. This is the default value.</li> </ul> |

- `:static` Allocate the array in a static segment.
  - `:long-lived` Allocate the array assuming it is going to be long-lived.
  - `:old` Same meaning as `:long-lived`
  - A fixnum  $n$  Allocate the array in generation  $n$ .
- Arrays (including strings) that are passed by address to foreign functions must be static, and so must should be created with `:allocation :static`.
- Allocation with `:old` or `:long-lived` is useful when you know that the array will be long-lived, because your program will avoid the overhead of promoting it to the older generations.

If *single-thread* is true then the system knows that *new-array* will always be accessed in a single thread context. That makes some operations faster, in particular `vector-pop` and `vector-push`. The default value of *single-thread* is `nil`.

|          |                                                                                                                                                    |

## make-hash-table *Function*

|           |                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | Creates and returns a new hash table which, in addition to the standard functionality, can have a user-defined test, a user-defined hash function, and be a weak hash table. |
| Package   | <code>common-lisp</code>                                                                                                                                                     |
| Signature | <code>make-hash-table &amp;key test size rehash-size rehash-threshold<br/>hash-function weak-kind single-thread free-function =&gt; hash-table</code>                        |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                        |

| Description | <p>The standard definition of <code>make-hash-table</code> is extended such that <i>test</i> can be any suitable user-defined function, except that it must not call <code>process-wait</code> or similar <code>mp</code> package functions which suspend the current process. If <i>test</i> is not one of the standard test functions (<code>eq</code>, <code>eql</code>, <code>equal</code> and <code>equalp</code>), and if <i>hash-function</i> is not supplied, then the hash value is the same as would be used if <i>test</i> were <code>equalp</code>.</p> <p><i>hash-function</i> may be supplied only if <i>test</i> is not one of the standard test functions. It takes a hash key as its argument and returns a hash value to use for hashing.</p> <p>If <i>weak-kind</i> is non-<code>nil</code>, it makes <i>hash-table</i> weak. Its semantics are the same as the second argument of <code>set-hash-table-weak</code>, that is:</p> |                                                                                                                                                                        |

```
(make-hash-table :weak-kind weak-kind <other-args>)
```

is equivalent to

```
(let ((ht (make-hash-table <other-args>)))
 (set-hash-table-weak ht weak-kind)
 ht)
```

The default value of *weak-kind* is `nil`.

*single-thread*, if true, tells `make-hash-table` that the table is going to be used only in single thread contexts, and therefore does not need to be thread-safe. Single thread context means

that only one thread can access the table at any point in time. That may be because the table is used only in one thread, but it can also be the case if the table is only ever accessed in the scope of a lock. Making a table with *single-thread* makes access to this table faster, but not thread-safe. It does not have other effects. The default value of *single-thread* is `nil`.

*free-function* adds a "free action" for a weak hash table. This has an effect only if `make-hash-table` is called with `weak-kind` non-`nil`. The *free-function* is called after an entry is automatically removed by the garbage collector (GC). If `weak-kind` is `nil`, *free-function* is ignored.

*free-function*, if supplied, must take two arguments: *key* and *value*. When an entry is removed from a weak table *hash-table* because the relevant object is not pointed by any other object, the *key* and the *value* are remembered. Some time later (normally short, but not well-defined) the *free-function* is called with *key* and *value* as its arguments.

*free-function* needs to be fast, to avoid delays in unexpected places. Otherwise there are no restrictions on what *free-function* does. In particular, it can keep the *key* or *value* alive by storing them somewhere.

When objects are removed from the table by explicit calls (`remhash`, `clrhash`, (`setf gethash`)), *free-function* is not called.

**Notes** Objects are removed from the table when the GC has identified them as free. For long-lived objects, which normally get promoted to higher generations, that may be quite a long time after the last pointer to them has gone.

*free-function* can also be specified in a call to `set-hash-table-weak`.

| <code><i>class</i></code>    | A class, or a symbol that names a class.                                                                                                                                                                                                                                                                                                                                                                                                                    |                           |                                          |                              |                                  |
| <code><i>initargs</i></code> | An initialization argument list.                                                                                                                                                                                                                                                                                                                                                                                                                            |                           |                                          |                              |                                  |
| Values                       | <code><i>instance</i></code> A fresh instance of class <code><i>class</i></code> .                                                                                                                                                                                                                                                                                                                                                                          |                           |                                          |                              |                                  |
| Description                  | <p><code>make-instance</code> behaves as specified in ANSI Common Lisp. In particular it checks the initialization arguments as calculated by <code>compute-class-potential-initargs</code>. This check can be suppressed by passing <code>:allow-other-keys t</code>. In addition, LispWorks provides global control over the initarg checking via <code>set-clos-initarg-checking</code> and per-class control via <code>class-extra-initargs</code>.</p> |                           |                                          |                              |                                  |
| Notes                        | In a delivered image, <code>make-instance</code> does not check the initialization arguments.                                                                                                                                                                                                                                                                                                                                                               |                           |                                          |                              |                                  |
| Compatibility                | In LispWorks 4.2 and previous versions, <code>make-instance</code> does not check the initargs. If your code contains invalid initargs, you could use one of the techniques mentioned above to resolve it.                                                                                                                                                                                                                                                  |                           |                                          |                              |                                  |
| Note                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                           |                                          |                              |                                  |

## **make-sequence** *Function*

Summary      Extends the standard `make-sequence` function allowing it to take any type specifier.

Package      `common-lisp`

Signature      `make-sequence result-type size &key initial-element => sequence`

Arguments      `result-type`      A type specifier.

`size`      A non-negative integer.

`initial-element`      An object.

Values      `sequence`      A sequence.

Description      The `make-sequence` function has been extended to take any Common Lisp type. The `sequence` will be of type `result-type` unless this is not possible, in which case a `type-error` is signalled.

                `map`  
                `merge`

## **map** *Function*

Summary      Redefines the standard `map` function allowing it to take any type specifier.

Package      `common-lisp`

| Values      | <i>stream</i> | A file stream, or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description |               | <p>If <i>external-format</i> has a name which is not <code>:default</code> and the parameters include <code>:eol-style</code>, it is used as is.</p> <p>Otherwise, the system decides which external format to use via <code>guess-external-format</code>. By default, this finds a match based on the filename; or (if that fails), looks in the EMACS-style (-*) attribute line for an option called <code>encoding</code> or <code>external-format</code>; or (if that fails), chooses from among likely encodings by analyzing the bytes near the start of the file. By default, it then also analyses the start of the file for byte patterns indicating the end-of-line style, and uses a default end-of-line style if no such pattern is found. This behavior is configurable.</p> <p>After the external-format has been determined, it is verified using <code>valid-external-format-p</code>; and an error is signalled if this check fails.</p> <p>If <code>open</code> gets <code>:default</code> as its <i>element-type</i> arg, it chooses the type on the basis of the external format. If <code>open</code> gets an <i>element-type</i> other than <code>:default</code> and the direction is <code>:input</code> or <code>:io</code>, the argument must be a supertype of the type of characters produced by the external format; if the direction is <code>:output</code> or <code>:io</code>, it must be a subtype of the type of characters accepted by the external format; if it does not satisfy these requirements, an error is signalled.</p> <p>Standard stream input and output functions for character and binary data generally work in the obvious way on a <code>file-stream</code> with <i>element-type</i> <code>base-char</code>, <code>(unsigned-byte 8)</code> or <code>(signed-byte 8)</code>. For example, <code>read-sequence</code> can be called with a string buffer and a binary <code>file-stream</code>: the character data is constructed from the input as if by <code>code-char</code>. Similarly <code>write-sequence</code> can be called with a string buffer and a binary <code>file-stream</code>: the output is converted from the character data as if by</p> |

`char-code`. Also, 8-bit binary data can be read from and written to a `base-char file-stream`.

All standard stream I/O functions except for `write-byte` and `read-byte` have this flexibility.

## open-stream-p

## *Generic Function*

**Summary** A generic function that determines if a stream has been closed.

## Package common-lisp

**Signature**      `open-stream-p stream => result`

Arguments      *stream*      A stream.

**Values**      *result*      A generalized boolean.

**Description** The function `open-stream-p` is generic. The default method provided by the class `fundamental-stream` returns `t` if `close` has not been called on the stream.

## output-stream-p

## Generic Function

**Summary** A generic function that determines if an object is an output stream.

| Values      | <code>result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | A generalized boolean. |
| Description | <p>The predicate <code>output-stream-p</code> is implemented as a generic function. The default method returns <code>t</code> if <code>stream</code> is an output stream. If the user wants to implement a stream with no inherent directionality (and thus does not include <code>fundamental-input-stream</code> or <code>fundamental-output-stream</code>) but for which the directionality depends on the instance, then a method should be provided for <code>output-stream-p</code>.</p> <p>There is an example in “Stream directionality” on page 276.</p> |                        |
| See also    | <code>fundamental-output-stream</code><br><code>input-stream-p</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                        |

| <b>proclaim</b> | <i>Function</i>                                                                                                                                                                                                |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary         | Established a specified declaration in the global environment.                                                                                                                                                 |
| Package         | <code>common-lisp</code>                                                                                                                                                                                       |
| Signature       | <code>proclaim declaration-list =&gt; nil</code>                                                                                                                                                               |
| Arguments       | <code>declaration-list</code> A list of declaration forms to be put into immediate and pervasive effect.                                                                                                       |
| Values          | Returns <code>nil</code> .                                                                                                                                                                                     |
| Description     | Unlike <code>declare</code> , <code>proclaim</code> is a function that parses the declarations in the list (usually a quoted list), and puts their semantics and advice into global effect. This can be useful |

when compiling a file for speedy execution, since a proclamation such as:

```
(proclaim '(optimize (speed 3) (space 0) (debug 0)))
```

means the rest of the file is compiled with these optimization levels in effect. Other ways of doing this are:

- use the `:optimize` option in `defsystem` to establish default optimization qualities for every member of the system, when compiled via `compile-system`.
- add appropriate `declare` declarations in every function in the file.

As `proclaim` involves parsing a list of lists of symbols and is intended to be used a few times per file at most, its implementation is not optimized for speed - it makes little sense to use it other than at top level.

**Note:** For a top-level call to `proclaim` or `declare`, optimize declarations are omitted from the compiled binary file. This deviates from the ANSI Common Lisp Standard but is useful because you are unlikely to want to change settings outside of that file. To make the global settings, you can call a function which calls `proclaim` (so it is not a top-level call).

See “Compiler control” on page 88 for a more extended description of the compiler optimize qualities.

#### Examples

```
(proclaim '(special *fred*))
(proclaim '(type single-float x y z))
(proclaim '(optimize (safety 0) (speed 3))))
```

#### Notes

As `proclaim` involves parsing a list of lists of symbols and is intended to be used a few times per file, its implementation is not optimized for speed — it makes little sense to use it other than at top level.

Remember to quote the argument list if it is a constant list.

`(proclaim (special x))` attempts to call function `special`.

Exercise caution if you declare or proclaim variables to be special without regard to the naming convention that surrounds their names with asterisks.

| Description | The macro <code>restart-case</code> behaves as specified in the ANSI Common Lisp standard.<br><br>In addition to that specification, <i>report-expression</i> may be a form whose <code>car</code> is <code>list</code> . Such a form is evaluated when the restart is set up and is expected to return a list of a format string and format arguments. When the restart is asked to report, this is done by calling <code>format</code> on the stream, the format string and the format arguments. This is more efficient than specifying an equivalent function, because no function object is created. |

| <b>room</b> | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Description | <p>This function provides statistics on the current state of the storage, including the amount of space currently allocated, and the amount available for allocation.</p> <p>As outlined in the Common Lisp Hyperspec, the <code>room</code> function takes an optional argument which controls the level of detail it produces.</p> <p>Given an argument of <code>nil</code>, a summary of the total allocation in the entire heap (in kilobytes) is produced. The “allocated” figure only represents the amount of space allocated in heap segments that are writable, as opposed to read-only segments that hold some of the system code such as the garbage collector (GC) itself. The free space figure covers all the free space in all segments. To obtain these values programmatically, call <code>room-values</code>.</p> <p>When called without an argument, <code>room</code> additionally prints information on the distribution of space between the generations of the heap.</p> <p>When called with argument <code>t</code>, a breakdown of allocation in the individual segments of each generation is produced. Each segment is identified by its start address in memory. For each segment there is a free space threshold (the “minimum free space”)—when the available space in the segment falls below</p> |

this value, the GC takes action to attempt to free more space in this segment.

Two statistics about promotion are also reported on a per-segment basis: the number of sweeps that an object must survive in this generation before becoming eligible for promotion, and the total volume of objects that have survived for that long and are consequently awaiting promotion to the next generation. These statistics are not relevant for static segments, which are indicated as “static”.

`room` prints numbers in decimal format, except for the segment start addresses which it prints in hexadecimal format.

Examples

```

CL-USER 22 > (room nil)

Total Size 39424K, Allocated 32591K, Free 6461K

CL-USER 23 > (room)
Generation 0: Total Size 4394K, Allocated 952K, Free
3433K
Generation 1: Total Size 1397K, Allocated 795K, Free
589K

## short-float *Type*

|             |                                       |
|-------------|---------------------------------------|
| Summary     | A subtype of <a href="#">float</a> .  |
| Package     | <a href="#">common-lisp</a>           |
| Signature   | <a href="#">short-float</a>           |
| Description | A short float is an immediate object. |

`short-float` is disjoint from `double-float` in all LispWorks implementations in version 5.0 and later.

`short-float` is disjoint from `single-float` in all 32-bit LispWorks implementations, version 5.0 and later. In 64-bit LispWorks `short-float` is the same type as `single-float`.

|                    |                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Compatibility Note | In LispWorks 4.4 and previous on Windows and Linux platforms, <code>short-float</code> is the same type as <code>double-float</code> . |
| See also           | <code>double-float</code><br><code>long-float</code><br><code>parse-float</code><br><code>single-float</code>                          |

|             | <i>Function</i>                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Identifies the physical location of the computer.                                                                                                                                                                           |
| Package     | <code>common-lisp</code>                                                                                                                                                                                                    |
| Signature   | <code>short-site-name =&gt; description</code><br><code>(setf short-site-name) description =&gt; description</code>                                                                                                         |
| Arguments   | <code>description</code> A string or <code>nil</code> .                                                                                                                                                                     |
| Description | The function <code>short-site-name</code> returns a string briefly identifying the physical location of the computer. This should be set using <code>(setf short-site-name)</code> when you configure your LispWorks image. |
| See also    | <code>long-site-name</code>                                                                                                                                                                                                 |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Type                                                        |

| Description               | The type of simple base strings.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                             |
| <b>single-float</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Type                                                        |
| Summary                   | A subtype of <code>float</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                             |
| Package                   | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                             |
| Signature                 | <code>single-float</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                                             |
| Description               | <p>A <code>single-float</code> is an immediate object in 64-bit LispWorks,<br/> A <code>single-float</code> is a boxed object in 32-bit LispWorks.<br/> <code>single-float</code> is disjoint from <code>double-float</code> in all LispWorks implementations, version 5.0 and later.<br/> <code>single-float</code> is disjoint from <code>short-float</code> in all 32-bit LispWorks implementations in version 5.0 and later. In 64-bit LispWorks <code>single-float</code> is the same type as <code>short-float</code>.</p> |                                                             |
| Compatibility             | In LispWorks 4.4 and previous on Windows and Linux platforms, <code>single-float</code> is the same type as <code>double-float</code> .                                                                                                                                                                                                                                                                                                                                                                                          |                                                             |
| Note                      | <p>However, there are distinct specialized array types<br/> <code>(array single-float)</code>, with single precision, and<br/> <code>(array double-float)</code>, with double precision.</p>                                                                                                                                                                                                                                                                                                                                     |                                                             |

| <b>step</b> | <i>Macro</i>                            |
|-------------|-----------------------------------------|
| Summary     | Steps through the evaluation of a form. |
| Package     | <code>common-lisp</code>                |

|             |                                                                                                                                                                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signature   | <b>step</b> <i>form =&gt; result</i>                                                                                                                                                                                                                  |
| Arguments   | <i>form</i> A form to be stepped and evaluated.                                                                                                                                                                                                       |
| Values      | <i>result</i> The values returned by <i>form</i> .                                                                                                                                                                                                    |
| Description | <b>step</b> evaluates a form and allows you to single-step through it. You can include a call to <b>step</b> inside a tricky definition to invoke the stepper every time the definition is used. <b>step</b> can also optionally step through macros. |

The commands shown below are available. When certain stepper variables (as described below) are set, some of these commands are not relevant and are therefore not available. Use **:help** to get a list of the commands.

- :s n** Step this form and all of its subforms (optional positive integer argument).
- :st** Step this form without stepping its subforms.
- :su** Step up out of this form without stepping its subforms.
- :sr** Return a value to use for this form.
- :sq** Quit from the current stepper level.
- :redo** Redo one of the previous commands.
- :get** Get an item from the history list and put it in a variable.
- :help** List available commands.
- :use** Replace one form with another form in previous command and redo it.
- :his** List the commands history.

The optional integer argument *n* for **:s** means do **:s n** times.

**Note:** `step` is a Listener-based form stepper. LispWorks also offers a graphical source-code Stepper tool. See the *LispWorks IDE User Guide* for details of that.

### Examples

The following examples illustrate some of these commands.

```
USER 12 > (step (+ 1 (* 2 3) 4))
(+ 1 (* 2 3) 4) -> :s
 1 -> :s
 1
 (* 2 3) -> :su
 6
 4 -> :s
 4
 11
 11

USER 13 > (defun foo (x y) (+ x y))
FOO

USER 14 > step (foo (+ 1 1) 2)
(FOO (+ 1 1) 2) -> :st
 (+ 1 1) -> :s
 1 -> :s
 1
 1 -> :s
 1
 2
 2 -> :s
 2
 4
 4
```

```
USER 15 > :redo (STEP (FOO # 2))
(FOO (+ 1 1) 2) -> :s
(+ 1 1) -> :s
 1 -> :s
 1
 2
 2 -> :s
 2
(+ X Y) -> :s
 X -> :s
 2
 Y -> :s
 2
 4
4
4
```

You can interact when an evaluated form returns, by setting the variable **\*no-step-out\*** to **nil**. The prompt changes as shown below:

```
USER 36 > step (cons 1 2)
(CONS 1 2) -> :s
 1 -> :s
 1 = 1 <- :sr 3
 2 -> :s
 2 = 2 <- :sr 4
(CONS 1 2) = (3 . 4) <- :s
(3 . 4)
```

To allow expansion of macros, set the variable **\*step-macros\*** to **t**.

To step through the function calls in compiled code, set the variable **hcl:\*step-compiled\*** to **t**.

If required, the stepper can print out the step level: set the variable **\*print-step-level\*** to **t**, as shown in this session:

```

USER 21 > (setq *print-step-level* t)
T
USER 22 > step (cons 1 2)
[1] (cons 1 2) -> :s
[2] 1 -> :s 1
[2] 2 -> :s
 2
 (1 . 2)
(1 . 2)

```

It is not advisable to try to step certain compiled functions, such as `car` and `format`. The variable `hcl:*step-filter*` contains a list of functions which should not be stepped. If you get deep stack overflows inside the stepper, you may need to add a function name to `hcl:*step-filter*`.

By default, the stepper uses the same printing environment as the rest of LispWorks (the same settings of the `*print-...*` variables). To control the stepper printing environment independently, set the variable `hcl:*step-print-env*` to `t`.

The values of the variables `hcl:*step-print-...*` are then used instead of the variables `*print-...*`.

|             |                     | <i>Generic Function</i>                                                                                                      |
|-------------|---------------------|------------------------------------------------------------------------------------------------------------------------------|
| Summary     |                     | Implements <code>stream-element-type</code> as a generic function.                                                           |
| Package     |                     | <code>common-lisp</code>                                                                                                     |
| Signature   |                     | <code>stream-element-type stream =&gt; type</code>                                                                           |
| Arguments   | <code>stream</code> | A stream.                                                                                                                    |
| Values      | <code>type</code>   | A type specifier.                                                                                                            |
| Description |                     | The function <code>stream-element-type</code> is implemented as a generic function. Depending on the stream, a method should |

be defined for this generic function that returns the element type of the stream.

Methods must be implemented for all subclasses of `buffered-stream`. Typically for character streams, the implementation can return the `array-element-type` of the buffer.

For the class `fundamental-character-stream` a default method is provided which returns `character`. A method should be defined for stream classes based on the `fundamental-binary-stream` class.

There is an example in “Recognizing the stream element type” on page 276.

| Arguments   | <code>length</code>                                                                                                                                                                                                                                                                  | The length of the string (or <code>*</code> , meaning any).                                                                        |
|             | <code>element-type</code>                                                                                                                                                                                                                                                            | The type of string element. The default is the value of <code>*default-character-element-type*</code> rather than <code>*</code> . |
| Description | The union of all string types as specified in the standard, but extended with an extra parameter: <code>element-type</code> .<br><br><code>(string <i>length element-type</i>)</code> means all string types whose element type is a subtype of <code>element-type</code> . That is: |                                                                                                                                    |

```
(string * base-char) = (vector base-char *)

(string * lw:simple-char) = (or (vector base-char *)
 (vector lw:simple-char *))

(string * character) = (or (vector base-char *)
 (vector lw:simple-char *)
 (vector character *))
```

```
Example CL-USER 235 > (lw:set-default-character-element-type
 'base-char)
BASE-CHAR
CL-USER 236 > (concatenate 'string "f" "o" "o")
"foo"
CL-USER 237 > (type-of *)
SIMPLE-BASE-STRING
```

|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Determines the execution time of a form in the current environment.                                                                                                                                                                                                                                                                              |
| Package     | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                         |
| Signature   | <code>time form =&gt; result</code>                                                                                                                                                                                                                                                                                                              |
| Arguments   | <code>form</code> A form to be evaluated.                                                                                                                                                                                                                                                                                                        |
| Values      | <code>result</code> The result of the evaluation of the form.                                                                                                                                                                                                                                                                                    |
| Description | <code>time</code> can be used to determine execution times. The macro evaluates the form <i>form</i> and returns its value <i>result</i> . <code>time</code> also prints some timing and size data: <i>user time</i> , <i>system time</i> , <i>elapsed time</i> , and the total amount of heap space allocated in executing the form (in bytes). |

The *user time* printed is the time used by LispWorks or any code that it calls in a dynamic library.

The *system time* printed is the time used in the operating system kernel when it is doing work on behalf of the LispWorks process.

The *elapsed time* printed is the time you could in principle measure with a stopwatch.

If LispWorks is 100% busy throughout the execution of the code, then *user time* + *system time* = *elapsed time*.

Each of the times is printed as:

- *secs.micros* if less than 60 seconds
- *hours:minutes:secs.micros* if 60 seconds or more.

The timing and size data covers all stack groups, not just the one that invokes `time`.

#### Notes

1. Note that `time` itself uses a small, constant amount of heap space.
2. `time` measures all threads, so to test accurately for consing in `code` you need to do:

```
(sys:with-other-threads-disabled (time code))
```

This is particularly important when using the LispWorks IDE. Do not use `with-other-threads-disabled` in your application code.

#### Examples

```
CL-USER 7 > (time (loop for i below 3000000
 sum (sqrt i)))
Timing the evaluation of (LOOP FOR I BELOW 3000000 SUM
 (SQRT I))

User time = 0:01:04.187
System time = 0.062
Elapsed time = 0:01:07.297
Allocation = 4932022956 bytes
0 Page faults
Calls to %EVAL 72000048
3.4606518E9
```

## trace *Macro*

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Summary   | Invoke the Common Lisp tracing facility on the named functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |
| Package   | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  |
| Signature | $\text{trace } \{\text{function-name} \mid \text{tracing-desc}\}^* \Rightarrow \text{trace-result}$ $\text{tracing-desc} ::= (\text{dspec } \{\text{keyword form}\}^*)$ $\text{dspec} ::= \text{function-name} \mid (\text{method generic-function-name } [\text{qualifier}] \ (class^*))$ $\text{keyword} ::= :after \mid :allocation \mid :before \mid :backtrace \mid :eval-after \mid :eval-before \mid :break \mid :break-on-exit \mid :entrycond \mid :exitcond \mid :inside \mid :process \mid :trace-output \mid :step \mid :when$ $\text{qualifier} ::= :after \mid :before \mid :around$ $\text{function-name} ::= \text{symbol} \mid (\text{setf symbol})$ |  |
| Arguments | <p><b><code>function-name</code></b>    A symbol whose symbol-function is to be traced, or a <code>setf</code> function name. Functions, macros and generic functions may be specified this way.</p> <p><b><code>dspec</code></b>        Specifies the functional definition which is to be traced. This either has the same form as above, or specifies a method by the name of its generic function and by a list of classes to specialize the arguments to the method. In this latter case the list of classes must correspond exactly to the classes of the special-</p>                                                                                          |  |

ized parameters of an existing method, and then only this method is traced (as opposed to the corresponding generic function).

*tracing-desc*      Specifies the functional definition which is to be traced and specifies any additional options that are required.

**:after** is followed by a list of forms; these are evaluated upon returning from the function. The values of these forms are also printed out by the tracer. The forms are evaluated after printing out the results of the function call, and if they modify **hcl:\*traced-results\*** then the values received by the caller of the function are correspondingly altered (see also **hcl:\*traced-results\***).

**:allocation** — if non-nil, the memory allocation made during a function-call is printed upon exit from the function. This allocation is counted in bytes. If it is any other symbol (except **nil**), **trace** uses the symbol to accumulate the amount of allocation made between entering and exiting the function. Upon exit from the function, the symbol contains the number of bytes allocated during the function-call. For example,

```
(trace (print :entrycond nil
 :exitcond nil
 :allocation $$print-allocation))
```

results in **\$\$print-allocation** containing the sum of the allocation made inside **print**.

Note that if the function is called again, **trace** continues to use **\$\$print-allocation** as an accumulator of memory allocation. It adds to the present value rather than re-initializing it each time the function is called.

**:backtrace** generates a backtrace on each call to the traced function. It is followed by a keyword that can be any of the following values:

**:quick**      Like the **:bq** debugger command.

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>t</b>                                   | Like the <code>:b</code> debugger command.                                                                                                                                                                                                                                                                                                                                                         |
| <b>:verbose</b>                            | Like the <code>:b :verbose</code> debugger command.                                                                                                                                                                                                                                                                                                                                                |
| <b>:bug-form</b>                           | Like the <code>:bug-form</code> debugger command.                                                                                                                                                                                                                                                                                                                                                  |
| <b>:before</b>                             | is followed by a list of forms; these are evaluated upon entering the function and their values are printed out by the tracer. The forms are evaluated after printing out the arguments to the function, and if they alter <code>*traced-arglist*</code> then the values received by the body of the function are changed accordingly (see also <code>*traced-arglist*</code> ).                   |
| <b>:eval-after</b> and <b>:eval-before</b> | are similar to <b>:after</b> and <b>:before</b> , without output.                                                                                                                                                                                                                                                                                                                                  |
| <b>:break</b>                              | is followed by a form. This is evaluated after printing the standard information caused by entering the function, and after executing any <code>:before</code> forms; if it returns <code>nil</code> then tracing continues normally, otherwise <code>break</code> is called. This provides a way of entering the debugger through the tracer.                                                     |
| <b>:break-on-exit</b>                      | is followed by a form. This is evaluated after printing the standard information caused by returning from the function, and before executing any <code>:after</code> forms; if it returns <code>nil</code> then tracing continues normally, otherwise <code>break</code> is called. This provides a second way of entering the debugger through the tracer.                                        |
| <b>:entrycond</b>                          | controls the printing of the standard entry message (including the function's arguments). If the form following it evaluates to give a non-nil value when the function is entered, then the entry message is printed (but otherwise it is not). If this option is not present then the standard entry message is always printed upon calling the function. See also the <code>:when</code> option. |
| <b>:exitcond</b>                           | controls the printing of the standard exit message (including the function's results). If the form following it evaluates to give a non-nil value when the function is exited, then the exit message is printed (but otherwise it is not). If this option is not present then the standard exit message is                                                                                         |

always printed upon returning from the function. See also the `:when` option.

`:inside` restricts the tracing to within one of the functions given as an argument. A single symbolic function name is treated as a list of one element. For example, `:inside format` is equivalent to `:inside (format)`.

`:process` may be used to restrict the tracing to a particular process. If it is followed by a process then the function is only traced when it is invoked from within that process. If it is followed by `t` then it is traced from all processes — this is the default. In any other cases the function is not traced at all.

`:trace-output` should be followed by a stream. All the output from tracing the function is sent to this stream. By default output from the tracer is sent to `*trace-output*`. Use of this argument allows you to dispatch traced output from different functions to different places.

`:step`, when non-nil, invokes the stepper (for evaluated functions).

`:when` overrides all other keywords. It is followed by an expression, and tracing only occurs when that expression evaluates to non-nil. It is useful if you want to combine `:entrycond` and `:exitcond`.

|             |                     |                                                                                                                                                                                                                                                                                                                                      |
|-------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <i>trace-result</i> | If <code>trace</code> is called with no arguments then it returns a list of the names of all the functions currently being traced. When called with one or more arguments, it returns the symbols of the functions specified in those arguments.                                                                                     |
| Description | <code>trace</code>  | <code>trace</code> is the macro used to invoke the tracing facility. This is a useful debugging tool that enables information about selected calls to be generated by the system. The standard way of invoking <code>trace</code> is to call it with the names of the functions, macros and methods that are to be monitored in this |

way. Calls to these produce a record of the function that was called, the arguments it received and the results it produced.

The arguments to `trace` each specify a function (or a macro or a method) to be traced. They may also contain further instructions to control how the tracing output is displayed, or to cause particular actions to occur when the functions is called or exited. If `trace` is called with a function that is already being traced, then the new tracing specification for that function replaces the old version.

|       |                                                                                                                                                                                                                |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes | For detailed information about the current tracing state, call <code>tracing-state</code> .<br><br>For information about problems with tracing and their resolution, see “Troubleshooting tracing” on page 49. |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Example 1

```
USER 1 > (defvar *number-of-calls-to-max* 0)
NUMBER-OF-CALLS-TO-MAX

USER 2 > (trace (max :after
 ((incf *number-of-calls-to-max*))))
(MAX)

USER 3 > (dotimes (i 2) (max i 1))
0 MAX > (0 1)
0 MAX < (1)
1
0 MAX > (1 1)
0 MAX < (1)
2
NIL

USER 4 > *number-of-calls-to-max*
2

USER 5 > (trace (max
 :entrycond
 (> (length compiler:*traced-arglist*)
 2)
 :exitcond nil))
(MAX)

USER 6 > (max 2 3 (max 4 5))
0 MAX > (2 3 5)
5
```

Example 2

This example illustrates the use of :inside.

```

CL-USER 2 > (defun outer ()
 (inner))
OUTER

CL-USER 3 > (defun inner ()
 10)
INNER

CL-USER 4 > (trace (inner :inside outer))
 ;; only trace when inside OUTER
(INNER)

CL-USER 5 > (inner)
 ;; no tracing occurs since we are not inside OUTER
10

CL-USER 6 > (outer) ;; INNER is traced inside OUTER
0 INNER > NIL
0 INNER < (10)
10

CL-USER 7 >

```

Example 3 To trace a method:

```

(defmethod foo (x) x)

(trace ((method foo (t))))

```

Example 4 To trace a setf function:

```

CL-USER 56 > (defvar *a* 0)
A

CL-USER 57 > (defun (setf foo) (x y) (set y x))
(SETF FOO)

CL-USER 58 > (trace (setf foo))
((SETF FOO))

CL-USER 59 > (setf (foo '*a*) 42)
0 (SETF FOO) > (42 *A*)
>> X : 42
>> Y : *A*
0 (SETF FOO) < (42)
42

```

## truename

*Function*

Summary

Returns the truename of a pathname.

Package

`common-lisp`

Signature

`truename filespec => truename`

Arguments

`filespec` A pathname designator.

Values

`truename` A fully-specified physical pathname.

Description

The function `truename` behaves as specified in ANSI Common Lisp. The returned value is a fully-specified pathname.

Truenames are always fully-specified in LispWorks (this prevents them from ever being corrupted by

`*default-pathname-defaults*`). Note that this means that the paths returned by `directory` are always fully specified.

See <code>trace</code> for more details. |
| <i>function-name</i> | A symbol whose symbol-function is no longer to be traced.                                                                                                                                                                                                                                                                                                |                      |                                                           |                    |                                                                                                                   |
| <i>method-desc</i>   | A method description, as described in the entry for <code>trace</code> . See <code>trace</code> for more details.                                                                                                                                                                                                                                        |                      |                                                           |                    |                                                                                                                   |
| Values               | When called with no arguments, it returns the symbols of all functions currently being traced. When called with one or more functions as arguments, <code>untrace</code> returns a list of the symbols of those functions. Thus, in all situations, <code>untrace</code> returns a list of the symbols of those functions being untraced.                |                      |                                                           |                    |                                                                                                                   |
| Description          | <code>untrace</code> is used to cease the tracing of functions. If it is called with no arguments then the tracing of all currently traced functions is stopped. If it is called with one or more symbols then the tracing of those functions is stopped. A warning is given if <code>untrace</code> is called with a function that is not being traced. |                      |                                                           |                    |                                                                                                                   |
| Examples             | <pre>USER 12 &gt; (progn (untrace) (trace + - / *)) *</pre> <pre>USER 13 &gt; (+ 2 3) 0 + &gt; (2 3) 0 + &lt; (5) 5</pre>                                                                                                                                                                                                                                |                      |                                                           |                    |                                                                                                                   |

```
USER 14 > (untrace + -)
(* |/|)
```

```
USER 15 > (+ 2 3)
5
```

To untrace a method:

```
(untrace (clos:method foo (t)))
```

## update-instance-for-different-class

*Generic Function*

Summary

As specified for Common Lisp, and locks the redefined instance.

Package

`common-lisp`

Description

The generic function `update-instance-for-different-class` behaves as specified for ANSI Common Lisp.

During the operation of updating the instance, including the call to `update-instance-for-different-class`, the redefined instance is locked against access. Any other process that tries to access the instance will hang until the operation finishes. Therefore your methods must avoid doing anything that may wait for another process which may access the instance, as this would cause a deadlock.

| Package     | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description | The generic function <code>update-instance-for-redefined-class</code> behaves as specified for ANSI Common Lisp.<br><br>During the operation of updating the instance, including the call to <code>update-instance-for-redefined-class</code> , the redefined instance is locked against access. Any other process that tries to access the instance will hang until the operation finishes. Therefore your methods must avoid doing anything that may wait for another process which may access the instance, as this would cause a deadlock. |
| See also    | <code>update-instance-for-different-class</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## with-output-to-string *Macro*

|             |                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Creates a character output stream, performs a series of operations that may send results to this stream, and then closes the stream.                                                                                                                                                                                                                                                                  |
| Package     | <code>common-lisp</code>                                                                                                                                                                                                                                                                                                                                                                              |
| Signature   | <code>with-output-to-string (var &amp;optional string-form &amp;key element-type) declaration form =&gt; result</code>                                                                                                                                                                                                                                                                                |
| Description | The macro <code>with-output-to-string</code> behaves as specified in the ANSI Common Lisp Standard with one exception: the default value of <code>element-type</code> is the value of <code>*default-character-element-type*</code> .<br><br>Therefore for strict compliance you must call <code>set-default-character-element-type</code> to set the default string type to <code>character</code> . |
| See also    | <code>compile-file</code><br><code>declare</code>                                                                                                                                                                                                                                                                                                                                                     |

```
proclaim
default-character-element-type
set-default-character-element-type

## The COMPILER Package

This chapter describes symbols available in the `COMPILER` package.

The compiler is discussed in detail in Chapter 9, “The Compiler”.

| deftransform |                                                                                                   | <i>Macro</i>                                                                                                                                                        |
|--------------|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary      | Defines a function that computes the expansion of a form.                                         |                                                                                                                                                                     |
| Package      | <code>compiler</code>                                                                             |                                                                                                                                                                     |
| Signature    | <code>deftransform name transform-name lambda-list &amp;body body =&gt; list-of-transforms</code> |                                                                                                                                                                     |
| Arguments    | <code>name</code>                                                                                 | A symbol naming the function to which the transform is to be applied.                                                                                               |
|              | <code>transform-name</code>                                                                       | The symbol naming the transformation — it should be unique for the function being transformed — and provides a handle with which to redefine an existing transform. |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>lambda-list</i> | This must match against the form being expanded before expansion is allowed to take place, in the sense that it must be valid to call a function with such a lambda list using the arguments supplied in the candidate-form for expansion.                                                                                                                                                                                                                                                                                         |
| <i>body</i>        | The body of the expander function, the result of which replaces the original form (unless it evaluates to <code>compiler::%pass%</code> , in which case no transformation is applied).                                                                                                                                                                                                                                                                                                                                             |
| Values             | <i>list-of-transforms</i> A list of the names of transforms defined for the function, including the one just added.                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description        | <code>deftransform</code> , like <code>defmacro</code> , defines a function that computes the expansion of a form. Transforms are only used by the compiler and not by the interpreter. <code>deftransform</code> allows you to add to the optimizations performed by the compiler.                                                                                                                                                                                                                                                |
| Examples           | <pre>(compiler:deftransform +  +-of-2  (x y)   '(system:: +2  ,x ,y)) (compiler:deftransform +  +-of-many (x &amp;rest y)   '(system:: +2  ,x (+ ,@y)))  ;; now an expression like (+ a b c 4 5 7 d e f) ;; compiles to use the binary version ;; of + (inlined by default), ;; rather than the full (slow) version of + (compiler:deftransform list  list-of-1 (x)   '(cons ,x '()))  (compiler:deftransform list  list-of-2 (x y)   '(cons ,x (cons ,y '())))  ;; save having to call list - ;; cons is inlined by default</pre> |

```

(compiler:deftransform constant my-trans (x)
 (cond ((constantp x) x)
 ((consp x) '(quote ,(eval x)))
 (t 'compiler::%pass%)) ; give up if not a
cons

(compile (defun three-list () (constant (list 1 2 3)))))

;; the function three-list returns the
;; same list (1 2 3)
;; every time it is called...

```

The `list-of-2` example returns

```
(LIST-OF-2 LIST-OF-1 COMPILER::LIST-TRANSFORM)
```

as its result, since a similar transform already exists in the compiler, by the name `compiler::list*-transform`.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <p><code>deftransform</code> differs from <code>defmacro</code> in various ways:</p> <p>The evaluation of the body can return <code>compiler:%pass%</code> indicating that the form is not to be expanded (in other words, the transform method has elected to give up trying to improve the code).</p> <p>The compiler only calls the expander function if the arguments match the lambda list — macros are unconditionally expanded.</p> <p>There can be several <code>deftransforms</code> for the same symbol, each having a different name. (The compiler calls each one in turn until one succeeds. This repeats until they all pass, so that the replacement form may itself be transformed.)</p> <p>If a transform takes keyword arguments the compiler preserves the correct order of evaluation.</p> <p>A carelessly written <code>deftransform</code> may lead the compiler to transform valid Common Lisp into incorrect code — there is no semantic checking of the transform.</p> |
| See also | <p><code>compile</code></p> <p><code>compile-file</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## The DBG Package

This chapter describes symbols available in the `DBG` package, used to configure the debugging information produced by LispWorks.

The debugger is discussed in detail in Chapter 3, “The Debugger”.

| <b>*debug-print-length*</b> |                                                                      | <i>Variable</i>                                                                                                                                                                                                                                                                      |
|-----------------------------|----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary                     | Controls the number of object components printed in debugger output. |                                                                                                                                                                                                                                                                                      |
| Package                     | <code>dbg</code>                                                     |                                                                                                                                                                                                                                                                                      |
| Initial Value               | <code>40</code>                                                      |                                                                                                                                                                                                                                                                                      |
| Description                 |                                                                      | This variable is used to control the number of components of an object which are printed during output from the debugger. If its value is a positive integer then the components up to that number are printed. If it is <code>nil</code> then all the parts of an object are shown. |
| Examples                    |                                                                      | <code>USER 83 &gt; (setq dbg:*debug-print-length* 3)</code>                                                                                                                                                                                                                          |

```

3
USER 84 > (aref
'(1 2 3 4 "Jenny" "cottage" "door")
2)

Error: (1 2 3 4 Jenny cottage door) must be
 an array
1 (abort) return to top loop level 0.

Type :c followed by a number to proceed

USER 85 : 1 > :v
Call to ARRAY-ACCESS :
Arg 0 (ARRAY): (1 2 3 ...)
Arg 1 (SUBSCRIPTS): (2)
Arg 2 (SET-P): NIL Arg 3 (VALUE): NIL

```

Notes      \***debug-print-length**\* is an extension to Common Lisp.

| <b>*debug-print-level*</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <i>Variable</i> |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary                    | Controls the depth to which nested objects are printed in debugger output.                                                                                                                                                                                                                                                                                                                                                                                                                     |                 |
| Package                    | <b>dbg</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                 |
| Initial Value              | 4                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                 |
| Description                | <b>dbg:*</b> <b>debug-print-level</b> <b>*</b> controls the depth to which nested objects are printed during output from the debugger. If its value is a positive integer then components at or above that level are printed. By definition an object to be printed is considered to be at level 0, its components are at level 1, their subcomponents are at level 2, and so on. If <b>dbg:*</b> <b>debug-print-level</b> <b>*</b> is <b>nil</b> then objects are printed to arbitrary depth. |                 |
| Example                    | USER 89 > ( <b>setq</b> <b>dbg:*</b> <b>debug-print-level</b> <b>*</b> 2)                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |

```

2
USER 90 > (subseq 3 '(cat (dog) ((goldfish))
 (((hamster)))))

Error: Illegal START argument (CAT (DOG)
 ((GOLDFISH))
 (((HAMSTER))))
1 (abort) return to top loop level 0.

Type :c followed by a number to proceed

USER 91 : 1 > :v
Call to CHECK-START-AND-END :
Arg 0 (START): (CAT (DOG) (#) (#))
Arg 1 (END): NIL

```

Notes      \***debug-print-level**\* is an extension to Common Lisp.

## **executable-log-file**                          *Function*

Summary     Returns the default bug form log file.

Package     **dbg**

Signature    **executable-log-file => log-file**

Values       *log-file*                          A pathname.

Description    The function **executable-log-file** returns the default bug form log file for the current executable, which is the default path for **\*hidden-packages\***

The path is also user specific.

See also     **\*hidden-packages\***  
**logs-directory**

| <b>*hidden-packages*</b> |                                                                                                                                                                                                                                                                                                                                                                                        | <i>Variable</i> |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary                  | A list of packages whose symbols should not be displayed in debugger output.                                                                                                                                                                                                                                                                                                           |                 |
| Package                  | <code>dbg</code>                                                                                                                                                                                                                                                                                                                                                                       |                 |
| Initial Value            | A list containing the <code>dbg</code> and <code>conditions</code> packages.                                                                                                                                                                                                                                                                                                           |                 |
| Description              | <code>dbg: *hidden-packages*</code> is used by the debugger. It should be bound to a list of package specifiers. If a package is included in the list then any symbols in it are not shown by the debugger. Thus during backtraces the call frames corresponding to functions in these packages are not displayed. This can be useful in restricting the debugger to particular areas. |                 |

Example      CL-USER 1 > unbound

```
Error: The variable UNBOUND is unbound.
 1 (continue) Try evaluating UNBOUND again.
 2 Return the value of :UNBOUND instead.
 3 Specify a value to use this time instead of
evaluating UNBOUND.
 4 Specify a value to set UNBOUND to.
 5 (abort) Return to level 0.
 6 Return to top loop level 0.

Type :b for backtrace or :c <option number> to proceed.
Type :bug-form "<subject>" for a bug report template or
?: for other options.

CL-USER 2 : 1 > :b 3
Call to ERROR
Call to EVAL
Call to CAPI::CAPI-TOP-LEVEL-FUNCTION

CL-USER 3 : 1 > (push "COMMON-LISP" dbg::*hidden-
packages*)
("COMMON-LISP" #<The COMPILER package, 3131/4096
internal, 41/64 external> #<The SYSTEM package,
6258/8192 internal, 1266/2048 external> "DBG"
"CONDITIONS")

CL-USER 4 : 1 > :b 3
Call to CAPI::CAPI-TOP-LEVEL-FUNCTION
Call to CAPI::INTERACTIVE-PANE-TOP-LOOP
Call to MP::PROCESS-SG-FUNCTION

| Description | <p>The function <code>log-bug-form</code> is a simple interface for writing a log of an error. Your application's error handlers can call it.</p> <p><code>log-bug-form</code> opens the file <i>log-file</i> for output. It writes the current date followed by a bug form. The bug form contains <i>description</i>, and debugging information generated by the system. When it finishes it writes to the stream <i>message-stream</i> a single line reporting that a bug form was written.</p> <p>If <i>log-file</i> is supplied it must be a valid path, and it is used to open the file. The default value of <i>log-file</i> is the value returned by <code>executable-log-file</code>.</p> <p><i>log-bug-form</i> calls <code>ensure-directories-exist</code> before opening the log file, therefore so the directory where the <i>log-file</i> is written does not need to exist before <code>log-bug-form</code> is called.</p> <p>If <i>message-stream</i> is <code>t</code> the message is written to standard output. If <i>message-stream</i> is a stream the message is written to it, and if <i>message-stream</i> is <code>nil</code> then no message is written.</p> <p>If there is an error during the operation, <code>log-bug-form</code> silently fails and returns <code>nil</code>.</p> <p>On success <code>log-bug-form</code> returns the path where the log file was written.</p> <p>See also the section "Reporting bugs" in the <i>LispWorks Release Notes and Installation Guide</i>.</p> |                                                        |
| Notes       | <p><code>log-bug-form</code> is invoked automatically if the debugger decides to use the console (the terminal) rather than use the</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                        |

LispWorks IDE debugging tools. This means that after such an error the user can always find a bug form in the default log file, which can be found by using `executable-log-file`.

`log-bug-form` always appends, so if it is called frequently the log file grows continuously. You may need to clear it periodically. It may be a good idea to move the file rather than delete it, so a record of errors remains.

When editing the log file it should be noted that each bug-form is preceded by the time it was written, and that the bug forms are in chronological order. That means that the interesting bug form is most often the last one in the file.

## **logs-directory** *Function*

Summary      Returns the directory in which LispWorks puts log files.

Package      `dbg`

Signature      `logs-directory => dir`

Values      `dir`      A directory pathname.

Description      The function `logs-directory` returns the directory in which LispWorks puts log files for the current user.

| Summary     | Prints a backtrace of the current stack. For use in exception handling routines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Package     | <code>dbg</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Signature   | <code>output-backtrace keyword &amp;key stream printer-bindings</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Arguments   | <p><i>keyword</i>      Defines how verbose the output should be.<br/>           It can be one of <code>:quick</code>, <code>:brief</code>, <code>:verbose</code> or <code>:bug-form</code>, in increasing order of verbosity.</p> <p><i>stream</i>      An output stream designator.</p> <p><i>printer-bindings</i> A list of conses.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description | <p>The function <code>output-backtrace</code> prints a backtrace of the current stack.</p> <p>The output goes to the stream designated by <i>stream</i>.</p> <p><i>printer-bindings</i>, if supplied, must be a list of conses, where the car of each cons is a symbol. <i>printer-bindings</i> is ignored if <i>keyword</i> is <code>:quick</code>. Otherwise, around the actual printing it binds each symbol to the value in the cdr of the cons. This is intended to override the bindings that are used in the functions that <code>output-backtrace</code> uses.</p> <p><code>output-backtrace</code> should be used by applications in their exception handling routines to log a backtrace whenever an unexpected situation arises. In general, any application that is not intended to be used by Lisp programmers should have error handlers to deal with unexpected situations, and all these handlers should use <code>output-backtrace</code>.</p> |
| Notes       | The symbols that can be bound are not limited to "printer" symbols, so the name <i>printer-bindings</i> is slightly misleading.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Initial Value                 | <code>nil</code>                                                |                                                                                                                                                                                                                                                                                             |
| Description                   |                                                                 | This variable is used by the debugger when it displays the stack frames. Binding frames are formed when special variables are bound, but are normally not shown by the debugger. However if the value of <code>dbg:*print-binding-frames*</code> is true then the binding frames are shown. |

## Example

```

CL-USER 16 > (defun print-to-length (object length)
 (let ((*print-length* length))
 (prinnt object)))
PRINT-TO-LENGTH

CL-USER 17 > (setf dbg:*print-binding-frames* t)
T

CL-USER 18 > (print-to-length '(x y z) 2)

Error: Undefined operator PRINNT in form (PRINNT
OBJECT) .
 1 (continue) Try invoking PRINNT again.
 2 Return some values from the form (PRINNT OBJECT) .
 3 Try invoking something other than PRINNT with the
same arguments.
 4 Set the symbol-function of PRINNT to another
function.
 5 Set the macro-function of PRINNT to another
function.
 6 (abort) Return to level 0.
 7 Return to top loop level 0.

Type :b for backtrace, :c <option number> to proceed,
or :? for other options

Notes      **\*print-binding-frames\*** is an extension to Common Lisp.

## **\*print-catch-frames\*** *Variable*

Summary    Controls whether catch frames are printed in debugger output.

Package    **dbg**

Initial Value    **t**

Description    This variable is used by the debugger when it displays the stack frames. Catch frames are created when the special form **catch** is used. They are set up so that throws to the matching tag can be received. By default the debugger displays these frames, but if **\*print-catch-frames\*** is set to **nil** then the catch frames are no longer shown.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Initial Value                                 | nil                                                                                                                                                                                                                                    |
| Description                                   | This variable is used by the debugger when it displays the stack frames. Handler frames are created by error handlers (see “The stack in the debugger” on page 12), and are normally not shown by the debugger. However if *print-han- |

`dler-frames*` is set to `t` then the handler frames are displayed.

Example

```
USER 162 > (setq lw:*print-handler-frames* t)

T
USER 163 > (defun test (n)
 (handler-case (fn-to-use n)
 (type-error () (format t "~%Type error~%") 0)))

TEST
USER 164 > (test #C(1 1))

Error: Undefined function: FN-TO-USE, with args
 (#C(1 1))

1 (continue) Call FN-TO-USE again
2 (abort) return to top loop level 0.

Type :c followed by a number to proceed

Notes `*print-restart-frames*` is an extension to Common Lisp.

| <b>*terminal-debugger-block-multiprocessing*</b> |                                                                                                                                                                                                | <i>Variable</i> |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary                                          | Controls blocking of multiprocessing in the terminal debugger.                                                                                                                                 |                 |
| Package                                          | <code>dbg</code>                                                                                                                                                                               |                 |
| Initial Value                                    | <code>t</code>                                                                                                                                                                                 |                 |
| Description                                      | When the debugger is entered on the terminal, multiprocessing is blocked if the value of <code>*terminal-debugger-block-multiprocessing*</code> is <code>t</code> . This is the default value. |                 |

If you set this variable to `nil` then other processes, including timers, will continue to run in parallel to the process that entered the terminal debugger (as they did before the debugger was entered). Beware that this will make it more difficult to debug multiprocess activities.

The other allowed value is `:maybe`. This means that multiprocessing is blocked in the terminal debugger unless the debugger was entered from the CAPI environment.

The value of

`*terminal-debugger-block-multiprocessing*` affects the behavior of a REPL started by `start-tty-listener`.

#### Example

This listener session illustrates the effect of `*terminal-debugger-block-multiprocessing*`.

Firstly we see the default behavior whereby a call to `print` in another process is blocked by the debugger.

```
CL-USER 1 > dbg:*terminal-debugger-block-
multiprocessing*
T

CL-USER 2 > unbound

Error: The variable UNBOUND is unbound.
 1 (continue) Try evaluating UNBOUND again.
 2 Specify a value to use this time instead of
evaluating UNBOUND.
 3 Specify a value to set UNBOUND to.
 4 (abort) Return to level 0.
 5 Return to top-level loop.
 6 Return from multiprocessing.

Type :b for backtrace, :c <option number> to proceed,
or :? for other options

CL-USER 3 : 1 > (setq *timer* (mp:make-timer 'print
10))
Warning: Setting unbound variable *TIMER*
#<Time Event : PRINT>

CL-USER 4 : 1 > (mp:schedule-timer-relative *timer* 1)
#<Time Event : PRINT>

CL-USER 5 : 1 > :a
```

On leaving the debugger the output 10 from the call to `print` appears. Then we set `*terminal-debugger-block-multiprocessing*` to `nil` and repeat the commands:

```

CL-USER 6 >
10
(setf dbg:*terminal-debugger-block-multiprocessing*
nil)
NIL

CL-USER 7 > unbound

Error: The variable UNBOUND is unbound.
1 (continue) Try evaluating UNBOUND again.
2 Specify a value to use this time instead of
evaluating UNBOUND.
3 Specify a value to set UNBOUND to.
4 (abort) Return to level 0.
5 Return to top-level loop.
6 Return from multiprocessing.

Type :b for backtrace, :c <option number> to proceed,
or :? for other options

CL-USER 8 : 1 > (setq *timer* (mp:make-timer 'print
10))
#<Time Event : PRINT>

CL-USER 9 : 1 > (mp:schedule-timer-relative *timer* 1)
#<Time Event : PRINT>

CL-USER 10 : 1 >
10

```

Notice above that the output 10 from the call to `print` appears after 1 second, in the debugger. Multiprocessing was not blocked.

See also      `start-tty-listener`

## **with-debugger-wrapper**

*Macro*

Summary      Executes code with a "debugger wrapper" which is called only if the debugger is invoked during the execution.

Package      `dbg`

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                          |

| Description | <p>The macro <code>with-debugger-wrapper</code> executes forms in <i>body</i> with the function <i>wrapper</i> bound as a "debugger wrapper". This debugger wrapper takes effect only if the code in <i>body</i> tries to invoke the debugger (by a call to <code>invoke-debugger</code>), typically indirectly as a result of an error. Instead of entering the debugger, the debugger wrapper is called with two arguments: a function to call to enter the debugger, and the condition. The wrapper can do whatever is needed. If it wants to enter the debugger, it does it by calling its first argument with the second argument:</p> <pre>(funcall function condition)</pre> |                          |
| Example     | <p>Suppose that you run many processes in parallel with the same code. If the code is broken then every process will get an error. This example shows how a debugger wrapper can be used to keep a lock around entry to the debugger, so that the processes enter the debugger one by one. It contains firstly the "application code", then the debugger wrapper, and lastly forms which execute the application with or without the debugger wrapper.</p>                                                                                                                                                                                                                          |                          |

```

;::::::::::::::::::; application code ;::::::::::;
;::::::::::::::::::; (in-package "CL-USER")

(defglobal-parameter *a* 0)

(defun foo (index cons)
 (sys:atomic-push (* index *a*) (cdr cons)))

;; This gets the process function so we can pass
;; the wrapper function instead.
(defun my-run-processes (do-error &optional
 (process-function 'foo))
 (setq *a* (if do-error :do-error 7))
 (let ((cons (cons nil nil)))
 (dotimes (x 10)

## The DSPEC Package

This chapter describes symbols available in the `DSPEC` package.

The `dspec` system is discussed in detail in Chapter 7, “Dspecs: Tools for Handling Definitions”.

| <b>*active-finders*</b> |                                                                                                                                                                                                                                                                                                                          | <i>Variable</i> |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary                 | Controls how source finding operates.                                                                                                                                                                                                                                                                                    |                 |
| Package                 | <code>dspec</code>                                                                                                                                                                                                                                                                                                       |                 |
| Initial Value           | <code>(:internal)</code>                                                                                                                                                                                                                                                                                                 |                 |
| Description             | The <code>*active-finders*</code> variable controls how the functions <code>find-name-locations</code> and <code>find-dspec-locations</code> operate. This in turn controls source the finding commands in the LispWorks IDE. You can switch between different sources of location information by setting this variable. |                 |
|                         | The legal values for the elements of <code>*active-finders*</code> are:                                                                                                                                                                                                                                                  |                 |

|                                                                                                                                                                                                                                                                                       |                                                                                                                         |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>:internal</b>                                                                                                                                                                                                                                                                      | The internal database of definitions performed in this image.                                                           |
| <b>:tags</b>                                                                                                                                                                                                                                                                          | Prompt for a tags file, when first used.                                                                                |
| <b>pathname</b>                                                                                                                                                                                                                                                                       | Either a tags file or a tags database.<br>A tags database is a fasl file generated by <code>save-tags-database</code> . |
| The order of this list determines the order that the results from the finders are combined in — you would usually want <b>:internal</b> to be the first item on this list, as it contains the up-to-date information about the state of the image. More than one pathname is allowed. |                                                                                                                         |

| <i>location</i> | A pathname or a keyword.                                                                                                                                                   |                             |                          |             |                                  |  |
| <i>body</i>     | Forms, including defining forms.                                                                                                                                           |                             |                          |             |                                  |  |
| Values          | <i>result</i>                                                                                                                                                              | The result of <i>body</i> . |                          |             |                                  |  |
| Description     | The macro <code>at-location</code> informs the dspec system that the source for definitions done during the execution of <i>body</i> are at the location <i>location</i> . |                             |                          |             |                                  |  |

*location* is usually a pathname, for definitions occurring in a file or editor buffer with that pathname.

Other locations are reserved for internal use. These are:

An editor buffer Defined in an editor buffer with no pathname.

`:listener` Interactively defined.

`:unknown` Defined without dspec information being recorded.

`:implicit` An aggregate defined by the existence of a part.

`(:inside dspec loc)`

A subform of *dspec* at location *loc*.

## canonicalize-dspec

## *Function*

Summary      Returns the canonical form for a dspec.

Package      `dspec`

Signature      `canonicalize-dspec dspec => canonical-dspec`

Arguments      `dspec`      A dspec.

Values      `canonical-dspec`      A canonical dspec.

Description      The function `canonicalize-dspec` checks that *dspec* is syntactically correct and returns its canonical form if *dspec* is valid. Otherwise `canonicalize-dspec` returns `nil`.

`canonicalize-dspec` expands dspec aliases

|          |                                                                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Example  | <pre>CL-USER 12 &gt; (dspec:canonicalize-dspec 'foo) (FUNCTION FOO)  CL-USER 13 &gt; (dspec:canonicalize-dspec '(defmethod bar (list t))) (METHOD BAR (LIST T))</pre> |

| Values       | <i>result</i> The result of <i>body</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |              |          |             |                                                     |
| Description  | <p>The macro <b>def</b> informs the system that any definitions within <i>body</i> should be recorded as being within the dspec <i>dspec</i>. This means that when something attempts to locate such a definition, it should look for a definition named <i>dspec</i>.</p> <p>Use <b>def</b> to wrap a group of definitions so that source location for one of the group causes the LispWorks Editor to look for the dspec in the <b>def</b> instead. Typically you will also need a <b>define-form-parser</b> definition for the macro that expands into the <b>def</b>.</p> <p><i>dspec</i> can be non-canonical.</p> <p>You can also use <b>def</b> to provide a dspec for a definition that has its own class that has been defined with <b>define-dspec-</b></p> |              |          |             |                                                     |

`class`. In this case, you arrange to call `record-definition` with the same dspec as in the example below.

It is also possible to mix these cases, recording a dspec and also grouping inner definitions. For example `defstruct` does this, recording itself and also grouping definitions such as the constructor function.

In all cases, to make source location work in the LispWorks editor you typically also need a `define-form-parser` definition for the macro that expands into the `def`.

Example

```
(defmacro define-wibble (x y)
 `(~(dspec:def (define-wibble ,x)
 (set-wibble-definition ',x ',y (dspec:location)))))

(defun set-wibble-definition (x y loc)
 (when (record-definition `(define-wibble ,x) loc)
 ;; defining code here
))
```

`location`

## define-dspec-alias

*Macro*

Summary

Informs the dspec system that a definer expands into another definer.

Package

`dspec`

Signature

`define-dspec-alias name lambda-list &body body`

Arguments

*name*      A symbol naming a definer.

*lambda-list*      A list representing the parameters of a *name* dspec.

*body*      Forms evaluated to yield a dspec.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The macro <code>define-dspec-alias</code> works rather like <code>deftype</code>. Dspecs whose <code>car</code> is <i>name</i> should have parameters that match <i>lambda-list</i>. They will be canonicalized into the dspec returned by <i>body</i>.</p> <p><code>define-dspec-alias</code> is useful when you add a new way of making existing definitions with a new defining form that expands into a system-provided defining form. The dspec system should consider the new and system-provided definers as variant forms of the same dspec class. <code>define-dspec-alias</code> is used to convert one of them to the other during canonicalization by <code>canonicalize-dspec</code>.</p> |
| Example     | <code>defparameter</code> is pre-defined as an alias for <code>defvar</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| See also    | <code>canonicalize-dspec</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <i>prettyf</i>         | A function to return a prettier form of a dspec of the class                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>definedp</i>        | A function to decide if a dspec of the class currently has a definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>object-dspec</i>    | A function to return the dspec from an object if it was defined by the class                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>defined-parts</i>   | A function to return all the currently defined parts in the class for a given a primary-name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>aggregate-class</i> | The aggregate dspec class for a part dspec                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Description            | <p>The macro <code>define-dspec-class</code> defines a dspec class, providing handlers for definitions in that dspec class.</p> <p><code>define-dspec-class</code> defines <i>name</i> as a dspec class, inheriting from the dspec class <i>superspace</i>. <i>superspace</i> should be <code>nil</code> to define a new top-level dspec class.</p> <p><i>documentation</i> should be a string documenting the dspec class. For example "<code>My Objects</code>".</p> <p>After evaluating a <code>define-dspec-class</code> form, <i>name</i> can be used by defining forms to record locations of definitions of that dspec class name by calling <code>record-definition</code>.</p> <p>All of the remaining arguments described below can be omitted if not needed. The most important arguments for the LispWorks IDE are <i>definedp</i> and <i>undefiner</i>.</p> <p>If <i>undefiner</i> is given, its value must be a function of one argument. When LispWorks wants to remove a definition, it will call the function with a canonical dspec of class <i>name</i>. The function should returns a form that removes the current definition of that dspec. For example, the undefining form for package dspecs might be <code>delete-package</code>. If <i>undefiner</i> is omitted, then definitions of this class cannot be undefined.</p> <p>If <i>canonicalize</i> is given, its value must be a function of one argument. The function will be called by <code>canonicalize-dspec</code> for a dspec of the given class. The value returned by</p> |

the canonicalize function must be a fully canonical dspec of the given class. A typical use for the canonicalize function would be to remove extra options from the dspec which are not required to make the dspec unique. The canonicalize function should return `nil` for malformed dspecs and should take care not to signal an error. The default canonicalize function returns the dspec if it matches the form

```
(dspec-class symbol)
```

If `prettify` is given, its value must be a function of one argument. When LispWorks wants to print a dspec, for example in an error message, it will call the prettify function for the class of the dspec. The argument will be the canonical dspec and the function should return a dspec which is considered "prettier" for a user to see. The default prettify function returns the dspec unchanged.

If `definedp` is given, its value must be function of one argument. When LispWorks wants to discover if a given dspec is defined, it calls the function with the `dspec-primary-name` of the dspec. The `definedp` function should return true if the primary name is defined in this dspec class and `nil` otherwise. The default `definedp` function always returns `nil`.

If `object-dspec` is given, its value must be a function of one argument. When LispWorks wants to find the dspec that created a given object (for example a package object created by a `defpackage` form), it calls the `object-dspec` functions in all dspec classes. The function should return a dspec for the object if that object was defined by the dspec class or `nil` otherwise. For example, the `object-dspec` function for package dspecs might be:

```
#'(lambda (obj)
 (and (packagep obj)
 ` (package , (package-name obj))))
```

The `object-dspec` function is used by the "Find Source" menu option in the Inspector in the LispWorks IDE to find where the current object was defined.

If *defined-parts* is given, its value must be a function of one argument. When LispWorks wants to find all the definitions that are parts of a given aggregate dspec class, it calls the *defined-parts* functions with the **dspec-primary-name** of the dspec in each class that aggregates with it. The function should return a list of dspecs which are defined parts of the primary name in the class *name*. If this keyword is given, *aggregate-class* must also be given.

If *aggregate-class* is given, its value must be a symbol naming a dspec class that is the aggregate class of the parts defined by *name* dspecs. For example, the aggregate class of **method** is **defgeneric** because methods are the defined parts of a particular generic function. If this keyword is given, the *defined-parts* must also be given.

To make **c1:documentation** work for your dspec class, add a suitable method as described for **documentation**.

Example See “Dspec classes” on page 63.

**record-definition**

## **define-form-parser** *Macro*

Summary Establishes a parser for top level forms with the given definier.

Package **dspec**

Signature **define-form-parser definer-and-options &optional parameters**  
**&body body => parser**

Arguments *definer-and-options*

|             |                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|             |                   | A symbol <i>definer</i> naming a definer of functions, macros, variables and so on, or a list ( <i>definer options</i> ) where <i>options</i> is a plist of keys and values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|             | <i>parameters</i> | <i>nil</i> , or list of parameters <i>params</i> in the top level form, optionally ending with <b>&amp;rest param-getter</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | <i>body</i>       | The body of a parser function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Values      | <i>parser</i>     | A form parser function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description |                   | <p>The macro <b>define-form-parser</b> defines a form parser for forms beginning with <i>definer</i>.<br/> <i>options</i> is a property list with the following keys allowed:</p> <ul style="list-style-type: none"> <li><b>:parser</b> A parser function <i>parser-function</i>.</li> <li><b>:alias</b> A dspec class or alias <i>alias</i>.</li> <li><b>:anonymous</b> A boolean.</li> </ul> <p>The parser function defined is named by <i>parser-function</i>. If the <b>:parser</b> option is omitted then the name defaults to a symbol in the current package whose symbol name is the symbol name of <i>definer</i> with "<b>-FORM-PARSER</b>" appended.</p> <p>If <i>parameters</i> and <i>body</i> are given, then <i>parser-function</i> is defined as a global function that is expected to return a dspec for the defining form or <b>nil</b> if this is not possible. Within <i>body</i>, <i>definer</i> is bound to the <b>car</b> of the actual form being parsed. In simple cases, this is just <i>definer</i>, but if the form parser is used as in the <b>:alias</b> option of another form parser then the symbol will be bound to the <b>car</b> of that form instead.</p> <p>The <i>params</i> are bound to subsequent subforms of the defining form. If <b>&amp;rest param-getter</b> is supplied, then it is bound to a function of no arguments that returns two values: the next</p> |

subform if there is one and a boolean to indicate if a subform was found.

If *parameters* and *body* are omitted, then *parser-function* is expected to be a form parser defined by a different `define-form-parser` form, or you can specify as an alias a definer with an existing form parser via the value *alias* of the `:alias` key in *options*.

If the `:anonymous` option is non-nil then *definer* is not associated with the form parser. This is useful in conjunction with *parameters* and *body* for defining generic form parsers that can be used in other `define-form-parser` forms.

LispWorks contains pre-defined form parser functions for the Common Lisp definers `defun`, `defmethod`, `defgeneric`, `defvar`, `defparameter`, `defconstant`, `defstruct`, `defclass`, `defmacro` and `deftype` and for LispWorks definers such as `fli:define-foreign-type` and `dspec:define-form-parser` itself.

When a defining symbol *definer* has an associated form parser, this parser function is used by the source location commands such as **Expression > Find Source** in the LispWorks IDE. Having identified the file where the definition was recorded, LispWorks parses the top level forms in the file looking for the one which matches the definition spec. When found, this match is displayed.

#### Example

Define a parser for `def-foo` forms which have a single name as the second element in the form:

```
(dspec:define-form-parser def-foo (name)
 `(&,def-foo ,name))
```

Define a parser for `def-other-foo` forms which are like `def-foo` forms:

```
(dspec:define-form-parser
 (def-other-foo (:parser def-foo-form-parser)))
```

Define a parser for **def-bar** forms whose name is made from the second element of the form and any subsequent keywords:

```
(dspec:define-form-parser def-bar (name &rest details)
 `,(def-bar (,name
 ,(loop for detail = (funcall details)
 while (keywordp detail)
 collect detail))))
```

Define a parser for forms which have another name as the second element in the form:

```
(dspec:define-form-parser (two-names
 (:anonymous t)) (name1 name2)
 `,(two-names ,name1 ,name2))
```

Define a new way to define CLOS methods, and tell the dspec system to treat them the same. Note the use of **define-dspec-alias** to inform the dspec system that **my-defmethod** is another way of naming **defmethod** dspecs:

```
(defmacro my-defmethod (name args &body body)
 `(defmethod ,name ,args
 ,@body))

(dsdp:define-dspec-alias my-defmethod
 (name &rest args)
 `(defmethod ,name ,@args))

(my-defmethod foo ((x number))
 42)

(dsdp:define-form-parser
 (my-defmethod
 (:parser
 #. (dsdp:get-form-parser 'defmethod))))
```

A simpler way to write the last form is:

```
(dsdp:define-form-parser
 (my-defmethod
 (:alias defmethod)))
```

|             | <i>Function</i>                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Clears the internal dspec database.                                                                                                                                        |
| Package     | <code>dspec</code>                                                                                                                                                         |
| Signature   | <code>discard-source-info =&gt; nil</code>                                                                                                                                 |
| Arguments   | None.                                                                                                                                                                      |
| Values      | Returns <code>nil</code> .                                                                                                                                                 |
| Description | The function <code>discard-source-info</code> removes all source location information from the internal dspec database.                                                    |
| Example     | To build <code>my-image</code> which does not contain source locations for the definitions loaded, but retaining a tags database of those definitions:                     |
|             | <pre>(load-all-patches) (load "my-code") (dsdp:save-tags-database   (compile-file-pathname #P"my-tags-database")) (dsdp:discard-source-info) (save-image "my-image")</pre> |
| See also    | <code>save-tags-database</code>                                                                                                                                            |

|           | <i>Function</i>                            |
|-----------|--------------------------------------------|
| Summary   | Returns the dspec class of a dspec.        |
| Package   | <code>dspec</code>                         |
| Signature | <code>dspec-class dspec =&gt; class</code> |
| Arguments | <code>dspec</code> A dspec.                |

|             |                    |                                                                                                                                                                                      |
|-------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <code>class</code> | A dspec class name.                                                                                                                                                                  |
| Description |                    | The function <code>dspec-class</code> returns the dspec class name for <i>dspec</i> .                                                                                                |
| Example     |                    | <pre>CL-USER 14 &gt; dspec:dspec-class 'foo FUNCTION  CL-USER 15 &gt; dspec:dspec-class '(defmacro foo) DEFMACRO  CL-USER 16 &gt; dspec:dspec-class '(defmethod foo) DEFMETHOD</pre> |
| See also    |                    | <code>dspec-name</code>                                                                                                                                                              |

### \***dspec-classes\*** *Variable*

|             |                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------|
| Summary     | Lists all the dspec classes.                                                                     |
| Package     | <code>dspec</code>                                                                               |
| Signature   | <code>*dspec-classes*</code>                                                                     |
| Description | The variable <code>*dspec-classes*</code> contains a list of the names of all the dspec classes. |

### **dspec-defined-p** *Function*

|           |                                                                 |
|-----------|-----------------------------------------------------------------|
| Summary   | The predicate for whether a dspec has a definition.             |
| Package   | <code>dspec</code>                                              |
| Signature | <code>dspec-defined-p <i>dspec</i> =&gt; <i>definedp</i></code> |
| Arguments | <code>dspec</code> A dspec.                                     |

|             |                       |                                                                                                                                                                                                                                                                        |
|-------------|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <code>definedp</code> | The canonical form of <i>dspec</i> if <i>dspec</i> is defined, or <code>nil</code> otherwise.                                                                                                                                                                          |
| Description |                       | The function <code>dspec-defined-p</code> determines whether the <i>dspec</i> <i>dspec</i> has a definition. If so, it returns the canonical form of <i>dspec</i> .<br><br>If <i>dspec</i> has no definitions, <code>dspec-defined-p</code> returns <code>nil</code> . |
| Example     |                       | <pre>CL-USER 23 &gt; (dspec:dspec-defined-p '(function list)) (DEFUN LIST)</pre>                                                                                                                                                                                       |

| <b>dspec-definition-locations</b> |                        | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary                           |                        | Returns the locations of the known definitions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Package                           | <code>dspec</code>     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Arguments                         | <code>dspec</code>     | A <i>dspec</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Values                            | <code>locations</code> | A list of pairs ( <i>recorded-dspec location</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description                       |                        | The function <code>dspec-definition-locations</code> returns the locations of the definitions recorded for the <i>dspec</i> <i>dspec</i> .<br><br>For each known definition <i>recorded-dspec</i> names the definition that defined <i>dspec</i> in <i>location</i> , and <i>location</i> is a pathname or keyword as described in <code>at-location</code> .<br><br>Note that non-file locations, such as <code>:unknown</code> , can occur in the list. The locations in <i>locations</i> are all basic locations: that is, there are no <code>(:inside ...)</code> locations.<br><br>If <i>dspec</i> is a local <i>dspec</i> , the parent function is located. |

Example      CL-USER 6 > (dspec:dspec-definition-locations  
                   ' (defun foo-bar))  
                   (((DEFSTRUCT FOO) #P"C:/temp/hack.lisp"))

## **dspec-equal** *Function*

Summary      Tests two dspecs for equality as dspecs.

Package      [dspec](#)

Signature      **dspec-equal *dspec1 dspec2* => *result***

Arguments      *dspec1, dspec2*      Dspecs.

Values      *result*      A boolean.

Description      The function **dspec-equal** compares *dspec1* and *dspec2* for equality as dspecs.

Both arguments are canonicalized before the comparison.

Dspecs in different subclasses of the same namespace are **dspec-equal** if their names match.

Unknown dspecs are compared simply by **equal**.

Example      CL-USER 44 > (dspec:dspec-equal '(deftype foo)  
                   '(defclass foo))  
                   T

## **dspec-name** *Function*

Summary      Extracts the name from a canonical dspec.

Package      [dspec](#)

|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary         | Returns the source location.                                                                                                                                                                                                                                                                                                        |
| Package         | <code>dspec</code>                                                                                                                                                                                                                                                                                                                  |
| Signature       | <code>location =&gt; location</code>                                                                                                                                                                                                                                                                                                |
| Values          | <code>location</code> A pathname or a keyword.                                                                                                                                                                                                                                                                                      |
| Description     | The macro <code>location</code> returns a location suitable for passing to <code>record-definition</code> . This is usually done via a separate defining function. You will need to use <code>location</code> only if you create your own ways of making definitions (and not if your definers call only system-provided definers). |
| Example         | <pre>(defmacro define-wibble (x y)   `(~(dspec:def (define-wibble ,x)     (set-wibble-definition ',x ',y (dspec:location)))))  (defun set-wibble-definition (x y loc)   (when (record-definition `(~(define-wibble ,x) loc)     ;; defining code here   )))</pre>                                                                   |
| See also        | <code>at-location</code><br><code>def</code>                                                                                                                                                                                                                                                                                        |

| <b>name-defined-dspecs</b> | <i>Function</i>                                            |
|----------------------------|------------------------------------------------------------|
| Summary                    | Returns defined dspecs matching a name.                    |
| Package                    | <code>dspec</code>                                         |
| Signature                  | <code>name-defined-dspecs classes name =&gt; dspecs</code> |
| Arguments                  | <code>classes</code> A list of dspec class names.          |

|             |               |                                                                                                                                                                                                                                                                         |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | <i>name</i>   | A name.                                                                                                                                                                                                                                                                 |
| Values      | <i>dspecs</i> | A list of canonical dspecs.                                                                                                                                                                                                                                             |
| Description |               | <p>The function <code>name-defined-dspecs</code> looks in each of the dspec classes <i>classes</i> for definitions of <i>name</i>.</p> <p>For each definition found (as if by <code>dspec-defined-p</code>), the result <i>dspecs</i> contains the canonical dspec.</p> |
| See also    |               | <code>dspec-defined-p</code>                                                                                                                                                                                                                                            |

| Arguments   | <i>classes</i>                                                                                                                                                                                                                                                                                                                                                                                       | A list of dspec class names.                        |
|             | <i>name</i>                                                                                                                                                                                                                                                                                                                                                                                          | A name.                                             |
| Values      | <i>locations</i>                                                                                                                                                                                                                                                                                                                                                                                     | A list of pairs ( <i>recorded-dspec location</i> ). |
| Description | <p>The function <code>name-definition-locations</code> returns the locations of the definitions recorded for the name <i>name</i> in any of the dspec classes in <i>classes</i>.</p> <p>For each known definition <i>recorded-dspec</i> names the definition that defined <i>name</i> in <i>location</i>, and <i>location</i> is a pathname or keyword as described in <code>at-location</code>.</p> |                                                     |
| Notes       | <code>name-definition-locations</code> does not use <code>*active-finders*</code> .                                                                                                                                                                                                                                                                                                                  |                                                     |

Example      CL-USER 7 > (dspec:name-definition-locations  
                  '(function) 'foo-bar)  
                  (((DEFSTRUCT FOO) #P"C:/temp/hack.lisp"))

## **name-only-form-parser** *Function*

Summary      A pre-defined form parser.

Package      [dspec](#)

Signature     [name-only-form-parser](#) *top-level-form getter* => [dspec](#)

Arguments     *top-level-form*    A top level defining form.

*getter*         The subform getter function.

Values        [dspec](#)        A dspec.

Description     The function [name-only-form-parser](#) is a predefined form parser for use with [define-form-parser](#). The parser consumes one subform and returns it.

[name-only-form-parser](#) can be used for function definitions where the function name is an abbreviation for the full dspec. It is the predefined parser for [defun](#), [defmacro](#) and [defgeneric](#) forms.

You can define it to be the parser for your defining forms. using [define-form-parser](#).

Example      (defmacro my-definer (name &body body)  
                  ` (defun ,name (x)  
                    ,@body))

```
(dspec:define-form-parser
 (my-definer (:parser
 dspec:name-only-form-parser)))
```

See also      **define-form-parser**

## **parse-form-dspec** *Function*

Summary      Parses the dspec from a defining form.

Package      **dspec**

Signature      **parse-form-dspec** *form* => *result*

Arguments      *form*                  A form.

Values      *result*                  A dspec or **nil**.

Description      The function **parse-form-dspec** invokes the defined form parser for *form* and returns the resulting dspec.

Example      

```
(parse-form-dspec '(def-foo my-foo (arg) (foo-it arg)))
=>
(def-foo my-foo)
```

See also      **define-form-parser**  
**get-form-parser**

## **record-definition** *Function*

Summary      Checks for existing definitions and records a new definition.

Package      **dspec**

Signature      **record-definition** *dspec* *location* &**key** *check-redefinition-p* => *result*

Arguments      *dspec*                  A dspec.

*location*               A pathname or keyword.

*check-redefinition-p*

A boolean.

|                    |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values             | <i>result</i> | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description        |               | <p>The function <code>record-definition</code> tells the system that <i>dspec</i> is defined at <i>location</i>.</p> <p>The system-provided definer macros call the function <code>record-definition</code> with the current location.</p> <p><i>location</i> should be a pathname or keyword as returned by <code>location</code>.</p> <p>When <i>check-redefinition-p</i> is true, it checks for existing definitions and reports these according to the value of <code>*redefinition-action*</code>. The default value of <i>check-redefinition-p</i> is <code>t</code>.</p> <p>If the definition is made, then <i>result</i> is true. If the definition is not made then <i>result</i> is <code>nil</code>. This can happen if you choose the "Don't redefine ..." restart at a redefinition error.</p> <p><b>Note:</b> You should not usually call <code>record-definition</code>, since all the system-provided definers call it. However, for new classes of definition which you add with <code>define-dspec-class</code>, you should call <code>record-definition</code> for <i>dspecs</i> in their new classes.</p> |
| Compatibility note |               | <p><code>record-definition</code> was documented in the <code>lispworks</code> package in LispWorks 4.3 and earlier. Although it is currently still available there, this may change in future releases and you should now reference it via the <code>dspec</code> package.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary            | Controls whether the locations of definitions are recorded.                                                                                                                                                                                                                   |
| Package            | <code>dspec</code>                                                                                                                                                                                                                                                            |
| Initial value      | <code>t</code>                                                                                                                                                                                                                                                                |
| Description        | The variable <code>*record-source-files*</code> controls whether locations of definitions are recorded in the internal tags database.                                                                                                                                         |
| Compatibility note | <code>*record-source-files*</code> was documented in the <code>lisp-works</code> package in LispWorks 4.3 and earlier. Although it is currently still available there, this may change in future releases and you should now reference it via the <code>dspec</code> package. |

| Initial value | <code>:warn</code>                                                                                                                                                                                                                                                                                                                                                                       |
| Description   | <code>*redefinition-action*</code> controls messages about redefinitions seen by the source location system.<br><br>If <code>*redefinition-action*</code> is set to <code>:warn</code> then you are warned. If it is set to <code>:quiet</code> or <code>nil</code> , the redefinition is done quietly. If, however, it is set to <code>:error</code> , then LispWorks signals an error. |

These messages are triggered by defining forms provided, but they could also be from any call to `record-definition`.

|                    |                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes              | <code>*redefinition-action*</code> does not affect the behavior of <code>cl:defstruct</code> .                                                                                                                                                                              |
| Compatibility note | <code>*redefinition-action*</code> is documented in the <code>lispworks</code> package in LispWorks 4.3 and earlier. It is still currently still available there but this may change in future releases and you should now reference it via the <code>dspec</code> package. |

| Values                         | <code>dspec</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | A dspec.                     |
| Description                    | <p>The function <code>single-form-form-parser</code> is a predefined form parser for use with <code>define-form-parser</code>. The parser consumes one subform and returns a dspec made from the defining form and the subform. This can be used in the common case where a defining form has a name that follows the defining macro and the dspec class is the same as the defining macro, for example <code>defclass</code>.</p> <p><code>single-form-form-parser</code> is the predefined parser for <code>defvar</code>, <code>defparameter</code>, <code>defconstant</code>, <code>define-symbol-macro</code>, <code>define-compiler-macro</code>, <code>deftype</code>, <code>defsetf</code>, <code>define-setf-expander</code>, <code>defpackage</code>, <code>defclass</code>, <code>define-condition</code> and <code>define-method-combination</code> top level forms. It is also the parser for various LispWorks extensions such as <code>defsystem</code>.</p> <p>You can define it to be the parser for your defining forms. using <code>define-form-parser</code>.</p> |                              |

| Values      | <code>dspec</code> A dspec.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description | <p>The function <code>single-form-with-options-form-parser</code> is a predefined form parser for use with <code>define-form-parser</code>. The parser consumes one subform and returns a dspec made from the defining form and either the first element of the subform if it is a cons or the subform itself otherwise. This can be used in the common case where a defining form has a name with options that follows the defining macro and the dspec class is the same as the defining macro, for example <code>defstruct</code>.</p> <p><code>single-form-with-options-form-parser</code> is the pre-defined parser for <code>defstruct</code>, <code>fli:define-foreign-function</code>, <code>fli:define-foreign-variable</code>, <code>fli:define-c-struct</code>, <code>fli:define-c-union</code>, <code>fli:define-c-enum</code> and <code>fli:define-c-typedef</code> forms.</p> <p>You can define it to be the parser for your defining forms. using <code>define-form-parser</code>.</p> |

| Summary     | Gets and sets the global tracing state..                                                                                                                                                                  |
| Package     | <code>dspec</code>                                                                                                                                                                                        |
| Signature   | <code>tracing-enabled-p =&gt; enabledp</code><br><code>(setf tracing-enabled-p) enabledp =&gt; enabledp</code>                                                                                            |
| Values      | <code>enabledp</code> A generalized boolean.                                                                                                                                                              |
| Description | The function <code>tracing-enabled-p</code> determines whether tracing (by the Common Lisp macro <code>trace</code> ) is currently on. This is independent of whether any functions are currently traced. |

The function (`(setf tracing-enabled-p)`) switches tracing on or off according to the value of *enabledp*. This does not affect the list of functions that are currently traced.

| Values      | <code>state</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | A list.                |
| Description | <p>The function <code>tracing-state</code> returns a listing describing the current state of the tracing system. It shows the current tracing state for the <code>dspec</code> <i>dspec</i>, or for all traced definitions if <i>dspec</i> is not supplied.</p> <p>The result <code>state</code> is a list each element of which is a list whose car is a <code>dspec</code> naming the traced definition and whose cdr is the additional trace options. Note that <code>tracing-state</code> returns more information than is returned by <code>trace</code>. It is useful for preserving a complex set of traces.</p> <p>The function (<code>(setf tracing-state)</code>) sets the state of the tracing system. It changes the current tracing state for the <code>dspec</code> <i>dspec</i>, or for all traced definitions if <i>dspec</i> is not supplied.</p> |                        |

(**setf tracing-state**) can be used to switch between different sets of traces. Note however that turning tracing on or off is better done using **tracing-enabled-p**.

## The EXTERNAL-FORMAT Package

This chapter describes symbols available in the `EXTERNAL-FORMAT` package. Use of these symbols are discussed in Chapter 22, “Internationalization”.

|           |                   | <i>Function</i>                                                                                                                                                                                                                                                                                                                                    |
|-----------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   |                   | Returns the code of a character in the specified character set.                                                                                                                                                                                                                                                                                    |
| Package   |                   | <code>external-format</code>                                                                                                                                                                                                                                                                                                                       |
| Signature |                   | <code>char-external-code char set =&gt; code</code>                                                                                                                                                                                                                                                                                                |
| Arguments | <code>char</code> | The character whose code you wish to return.                                                                                                                                                                                                                                                                                                       |
|           | <code>set</code>  | A character set. Legal values for <code>set</code> are <code>:unicode</code> , <code>:latin-1</code> , <code>:ascii</code> , <code>:macos-roman</code> , <code>:jis-x-208</code> , <code>:jis-x-212</code> , <code>:euc-jp</code> and <code>:sjis</code> . Additionally, on Windows, <code>set</code> can be a valid Windows code page identifier. |

| Values                                                                                                                                                                                                                                              | <code>code</code>                                                                                                                                                                                                              | The code of <i>char</i> in the character set <i>set</i> . An integer. |
| Description                                                                                                                                                                                                                                         | Returns the code of the character <i>char</i> in the coded character set specified by <i>set</i> , or <code>nil</code> , if there is no encoding. Note that a coded character set is not the same thing as an external format. |                                                                       |
| For the <i>set</i> parameter, the <code>:jis-*</code> codes are KUTEN indexes (from the 1990 version of these standards) encoded as                                                                                                                 |                                                                                                                                                                                                                                |                                                                       |
| <code>(+ (* 100 row) column)</code>                                                                                                                                                                                                                 |                                                                                                                                                                                                                                |                                                                       |
| <code>:euc-jp</code> is the complete two-byte format encoded as                                                                                                                                                                                     |                                                                                                                                                                                                                                |                                                                       |
| <code>(+ (* 256 first-byte) second-byte)</code>                                                                                                                                                                                                     |                                                                                                                                                                                                                                |                                                                       |
| <code>:sjis</code> is Shift-JIS encoded in the same way. Strictly speaking, EUC and Shift-JIS are not coded character sets, but encodings of the JIS sets, but the encoding is easily expressed as an integer, so the same interface to it is used. |                                                                                                                                                                                                                                |                                                                       |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description        | The function <code>decode-lisp-string</code> decodes the integers in the part of the vector <code>vector</code> bounded by <code>start</code> and <code>end</code> using encoding <code>external-format</code> to make a string <code>string</code> .<br><br>The element type of <code>vector</code> does not need to match the <code>external-format-foreign-type</code> of <code>external-format</code> . |
| Compatibility note | This function exists in LispWorks 5.0 but is not documented and does not take the <code>:start</code> and <code>:end</code> arguments. Also, it was inefficient prior to LispWorks 5.0.1.                                                                                                                                                                                                                   |

| <code>string</code>          | A string.                                                                                                                                                                                                                                                                                                                                                                      |                     |           |                              |                          |                         |                                                     |
| <code>external-format</code> | An external format spec.                                                                                                                                                                                                                                                                                                                                                       |                     |           |                              |                          |                         |                                                     |
| <code>start, end</code>      | Bounding index designators of <code>string</code> .                                                                                                                                                                                                                                                                                                                            |                     |           |                              |                          |                         |                                                     |
| Values                       | <code>vector</code><br>A binary vector.                                                                                                                                                                                                                                                                                                                                        |                     |           |                              |                          |                         |                                                     |
| Description                  | <p>The function <code>encode-lisp-string</code> converts the part of <code>string</code> bounded by <code>start</code> and <code>end</code> to a binary vector <code>vector</code> encoded in encoding <code>external-format</code>.</p> <p>The element type of <code>vector</code> matches the <code>external-format-foreign-type</code> of <code>external-format</code>.</p> |                     |           |                              |                          |                         |                                                     |

**Compatibility note** This function exists in LispWorks 5.0 but is not documented and does not take the `:start` and `:end` arguments. Also, it was inefficient prior to LispWorks 5.0.1.

## **external-format-error** *Condition*

**Summary** The condition class `external-format-error` is the superclass of all errors relating to external formats.

**Package** `external-format`

**Superclasses** `error`

**Initargs** `:name` The name of the external format involved.

**Description** The class `external-format-error` provides a slot for the name of external format involved: this is the fully expanded form of the specification with all the parameters filled in. It is also useful for users who want to set up a handler for encoding errors.

## **external-format-foreign-type** *Function*

**Summary** Returns a type specifier for the integers handled by a specified external format.

**Package** `external-format`

**Signature** `external-format-foreign-type external-format => type-specifier`

**Arguments** `external-format` An external character format.

|             |                       |                                                                                                                                                        |
|-------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <i>type-specifier</i> | A type specifier describing the integer types handled by <i>external-format</i> .                                                                      |
| Description |                       | Takes the name of an external format, and returns a Lisp type specifier for the type of integers that the external format handles on the foreign side. |
| See also    |                       | <code>external-format-type</code>                                                                                                                      |

This is an integer.                                                                                                                                                                                                                                                                                                                 |
|             | <code>set</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | A character set. Legal values for <code>set</code> are<br><code>:unicode</code> , <code>:latin-1</code> , <code>:ascii</code> , <code>:macos-roman</code> , <code>:jis-x-208</code> , <code>:jis-x-212</code> , <code>:euc-jp</code> and <code>:sjis</code> . Additionally, on Windows, <code>set</code> can be a valid Windows code page identifier. |
| Values      | <code>char</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | The character represented by <code>code</code> . If <code>code</code> is not a legal code in the specified set, the return value is undefined.                                                                                                                                                                                                        |
| Description | <p>Returns the character that has the code <code>code</code> (an integer) in the coded character set specified by <code>set</code>, or <code>nil</code>, if that character is not represented in the Lisp character set. Note that a coded character set is not the same thing as an external format.</p> <p>For the <code>set</code> parameter, the <code>:jis-*</code> codes are KUTEN indexes (from the 1990 version of these standards) encoded as</p> <pre>(+ (* 100 row) column)</pre> <p><code>:euc-jp</code> is the complete two-byte format encoded as</p> <pre>(+ (* 256 first-byte) second-byte)</pre> <p><code>:sjis</code> is Shift-JIS encoded in the same way. Strictly speaking, EUC and Shift-JIS are not coded character sets, but encodings of the JIS sets, but the encoding is easily expressed as an integer, so the same interface to it is used.</p> |                                                                                                                                                                                                                                                                                                                                                       |

## The HCL Package

This chapter describes symbols available in the `HCL` package. This package is used by default. Its symbols are visible in the `CL-USER` package.

Various uses of the symbols documented here are discussed throughout this manual.

|           |                                                                                 | <i>Function</i>                                                                                    |
|-----------|---------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| Summary   | Adds a function to perform a special action during garbage collection.          |                                                                                                    |
| Package   | <code>hcl</code>                                                                |                                                                                                    |
| Signature | <code>add-special-free-action <i>function</i> =&gt; <i>function-list</i></code> |                                                                                                    |
| Arguments | <i>function</i>                                                                 | A symbol naming a function of one argument.                                                        |
| Values    | <i>function-list</i>                                                            | A list of the functions currently called to perform special actions, including the one just added. |

|             |                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | When some objects are garbage collected, you may require a “special action” to be performed as well. <code>add-special-free-action</code> adds the function <i>function</i> to perform the special action. Note that the function is applied to all objects flagged for special-free-action, so the function <i>function</i> should check for the object’s type, so that it only affects relevant objects. |
|             | The functions <code>flag-special-free-action</code> and <code>flag-not-special-free-action</code> flag and unflag objects for action.                                                                                                                                                                                                                                                                      |
| Example     | <code>(add-special-free-action 'free-my-app)</code>                                                                                                                                                                                                                                                                                                                                                        |
| See also    | <code>remove-special-free-action</code><br><code>flag-special-free-action</code><br><code>flag-not-special-free-action</code>                                                                                                                                                                                                                                                                              |

|             | <i>Function</i>                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------|
| Summary     | Adds a symbol to the list of profiled symbols.                                                                       |
| Package     | <code>hcl</code>                                                                                                     |
| Signature   | <code>add-symbol-profiler symbol =&gt; nil</code>                                                                    |
| Arguments   | <code>symbol</code> A symbol to be added to the <code>*profile-symbol-list*</code> .                                 |
| Values      | Returns <code>nil</code> .                                                                                           |
| Description | <code>add-symbol-profiler</code> adds a symbol to <code>*profile-symbol-list*</code> , the list of profiled symbols. |
| See also    | <code>*profile-symbol-list*</code><br><code>remove-symbol-profiler</code>                                            |

|             |                                                                                                                                                                                                                                                                                                                                                | <i>Macro</i>                                                                                                                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Allocates objects from a specified generation within the scope of evaluating a number of forms in 32-bit LispWorks.                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                       |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                       |
| Signature   | <code>allocation-in-gen-num <i>gen-num</i> &amp;body <i>body</i> =&gt; <i>result</i></code>                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                       |
| Arguments   | <p><i>gen-num</i></p> <p>An integer, which if out of range for a valid generation number is rounded either to the youngest or oldest generation.</p> <p>If <i>gen-num</i> is negative, the specified generation is: the highest generation number + 1 – <i>gen-num</i>, so that an argument of -1 specifies the highest generation number.</p> |                                                                                                                                                                                                                                                                                                       |
|             | <i>body</i>                                                                                                                                                                                                                                                                                                                                    | The forms to be evaluated while the allocation generation has been temporarily set to <i>gen-num</i> .                                                                                                                                                                                                |
| Values      | <i>result</i>                                                                                                                                                                                                                                                                                                                                  | The result of evaluating body.                                                                                                                                                                                                                                                                        |
| Description | Allocates objects from a specified generation during the extent of the evaluation of the body forms.                                                                                                                                                                                                                                           | <p>Normally objects are allocated from the first (youngest) generation, which assumes that they are short-lived. The storage allocator and garbage collector perform better if allocation of large numbers of non-ephemeral objects is done explicitly into a generation other than the youngest.</p> |
| Notes       | <code>allocation-in-gen-num</code> is implemented only in 32-bit LispWorks. In 64-bit implementations, use <code>apply-with-allocation-in-gen-num</code> or the <code>:allocation</code> argument to <code>make-array</code> instead.                                                                                                          |                                                                                                                                                                                                                                                                                                       |

**Examples**

```
(allocation-in-gen-num
 1
 (setq tab (make-hash-table :size 1200
 :test 'eq)
 arr (make-array 20)))
```

**analysing-special-variables-usage***Function***Summary**

Prints an analysis of proclaimed symbols seen during compilation, as an aid to improving declarations.

**Package**

`hcl`

**Signature**

`analyzing-special-variables-usage (&key all default maybe-globals maybe-dynamics unused only-bound wrong-global inconsistent stream) &body body => results`

**Arguments**

*all* A boolean.

*default* A boolean.

*maybe-globals* A boolean.

*maybe-dynamics* A boolean.

*unused* A boolean.

*only-bound* A boolean.

*wrong-global* A boolean.

*inconsistent* A boolean.

*stream* `t` or an output stream.

*body* Lisp code that calls the compiler.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                      |

| Description | <p>The macro <code>analyzing-special-variables-usage</code> executes the code in <i>body</i>, which needs to call the compiler, typically many times (compiling a whole system, for example). When <i>body</i> exits, it prints a simple analysis of symbols that were proclaimed and how they were proclaimed, in a way that is intended to be helpful in improving declarations. For a full explanation of how you might add or alter declarations, see “Usage of special variables” on page 98.</p> <p>The analysis is based solely on what the compiler sees, ignoring what is already in the image. It also ignores inline declarations.</p> <p>Only symbols for which the compiler sees a special proclamation are reported (including <code>c1:defvar</code>, <code>c1:defparameter</code>, <code>defglobal-parameter</code> and <code>defglobal-variable</code>, but not <code>c1:defconstant</code>).</p> <p><i>all</i> and <i>default</i> are convenience arguments to control groups of the other keyword arguments, which are all boolean flags. The default value of <i>all</i> is <code>nil</code>. <i>all</i> provides the default value of <i>maybe-globals</i> and <i>maybe-dynamics</i>. The default value of <i>default</i> is <code>t</code>. <i>default</i> provides the default value of <i>unused</i>, <i>only-bound</i>, <i>wrong-global</i> and <i>inconsistent</i>.</p> <p><i>stream</i> determines where the analysis goes, and is interpreted as if by <code>c1:format</code>. It does not affect any of the I/O in <i>body</i>. The default value of <i>stream</i> is <code>t</code>, meaning standard output.</p> <p><i>inconsistent</i> controls whether to print symbols where the declaration and usage is inconsistent. Inconsistencies include:</p> <ol style="list-style-type: none"> <li>1. Accessing or binding the symbol before the proclamation.</li> <li>2. Multiple declarations which are different (for example, change from <code>hcl:special-dynamic</code> to <code>c1:special</code>)</li> </ol> <p>The <i>inconsistent</i> messages are the most useful. A well written program should not produce any such message.</p> |                                      |

*unused* controls whether to report symbols that are proclaimed special but are otherwise not used. For this option to be really useful, *body* needs to force compile many source files.

Since such unused variables do not affect the code, *unused* is normally useful only for finding and eliminating dead declarations, but it can also flag situations when the wrong variable is used (if the variable that is supposed to be used is not used elsewhere)

*only-bound* controls whether to report symbols that have been seen bound, but whose value has not been read. The comments about *unused* also apply to *only-bound*.

*wrong-global* controls whether to print symbols that are bound but are also proclaimed `hcl:special-global`. If the proclamation preceded the binding, the compiler will signal a `compiler-error`.

*maybe-globals* controls whether to report symbols that were not seen bound. If these symbols are really never bound, they can be proclaimed global by defining them with `defglobal-parameter` and `defglobal-variable`, or proclaimed `hcl:special-global`, both for speed and also to prevent them getting bound by mistake.

It is quite useful to force compile a program each now and then with *maybe-globals* true, then check through the report and proclaim global all those symbols that can be proclaimed global.

*maybe-dynamics* controls whether to report symbols that have been seen bound, and are proclaimed special, but not `hcl:special-dynamic` or `hcl:special-global`. Some of these may be proclaimed `hcl:special-dynamic`.

The report that is generated is grouped according to the file in which a proclamation was found. If a variable was proclaimed in multiple files, it will appear multiple times in the output. Within each file the output is grouped according to what is reported.

For the keyword arguments except *inconsistent*, the symbols are simply listed. For the *inconsistent* report, it outputs several lines for each symbol. Each line starts with one of the symbols `c1:special`, `hcl:special-global`, `hcl:special-dynamic`, `hcl:special-fast-access` (these four signify a proclamation), `:bound` or `:accessed` (these two indicate the usage). It is followed by the pathname of the file in which this one found. Only occurrences which give rise to inconsistency are listed.

|          |                                                                                                                                                                                                                                                                                                                                                                                     |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | The report about <i>inconsistent</i> usage is almost always useful. <i>unused</i> and <i>only-bound</i> are mostly useful when <i>body</i> force compiles many files, though they have limited utility in partial compilation too. <i>maybe-globals</i> and <i>maybe-dynamics</i> need full compilation to be really useful. Of the latter <i>maybe-globals</i> is the more useful. |

|             | <b>any-capi-window-displayed-p</b>                                                                                                            | <i>Function</i> |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary     | A predicate for whether any CAPI window is currently displayed.                                                                               |                 |
| Package     | <code>hcl</code>                                                                                                                              |                 |
| Signature   | <code>any-capi-window-displayed-p =&gt; result</code>                                                                                         |                 |
| Values      | <code>result</code>                                                                                                                           | A boolean.      |
| Description | The function <code>any-capi-window-displayed-p</code> is a predicate for whether any CAPI window (other than dialogs) is currently displayed. |                 |

- Notes
1. See the *LispWorks CAPI User Guide* for a description of the CAPI toolkit which allows you to write graphical user interfaces in Lisp.
  2. Tools in the LispWorks IDE are all CAPI windows.

## **array-single-thread-p** *Function*

Summary      The predicate for single-thread arrays.

Package      **hcl**

Signature      **array-single-thread-p array => result**

Arguments      **array**                  An array.

Values      **result**                  A boolean.

Description      The function **array-single-thread-p** is the predicate for whether an array is one known to be only accessed in a single thread context, as created by

(make-array ... :single-thread t)

or set by **set-array-single-thread-p**.

See also      **make-array**  
**set-array-single-thread-p**

## **array-weak-p** *Function*

Summary      The predicate for whether an object is a weak array.

Package      **hcl**

Signature      **array-weak-p object => result**

|             |               |                                                                                                                                     |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Arguments   | <i>object</i> | A Lisp object.                                                                                                                      |
| Values      | <i>result</i> | A boolean.                                                                                                                          |
| Description |               | The function <b>array-weak-p</b> returns <b>t</b> if its argument <i>object</i> is a weak array, and otherwise returns <b>nil</b> . |
| See also    |               | <b>make-array</b><br><b>set-array-weak</b>                                                                                          |

## **augment-environment** *Function*

**Summary** Returns a new environment based on an existing one with different bindings.

**Package** **hcl**

**Signature** **augment-environment** *env* &**key** *variable symbol-macro function macro declare reset => newenv*

|           |                     |                                  |
|-----------|---------------------|----------------------------------|
| Arguments | <i>env</i>          | An environment or nil            |
|           | <i>variable</i>     | A list of symbols                |
|           | <i>symbol-macro</i> | A list of lists                  |
|           | <i>function</i>     | A list of function names         |
|           | <i>macro</i>        | A list of lists                  |
|           | <i>declare</i>      | A list of declaration-specifiers |
|           | <i>reset</i>        | A generalized boolean            |

**Values** *newenv* An environment

**Description** The function **augment-environment** returns a new environment *newenv*, based on *env* but modified according to the keyword arguments *variable*, *symbol-macro*, *function*, *macro*, *declare* and *reset*.

If *env* is `nil`, then *newenv* will be based on the null environment. Otherwise, if *reset* is false (the default) then all of the bindings in *env* will be present in *newenv* unless overridden by the other keyword arguments. Otherwise, if *reset* is true then all of the non-local bindings in *env* will be present in *newenv* but none of the local bindings will be present. Passing *reset* as true allows you to create an environment object for calls to `variable-information` and so on which can access the file compilation environment without seeing local bindings in the lexical environment.

*variable* should be a list of symbols and *newenv* will contain these symbols as local variable bindings. A binding will be a special binding if the symbol is declared special non-lexically in *env* or a special declaration is present in *declare*.

*symbol-macro* should be a list of lists of the form (*symbol expansion*) and *newenv* will contain local symbol-macro bindings for each *symbol* with *expansion* as its macroexpansion.

*function* should be a list of function names and *newenv* will contain these symbols as local function bindings.

*macro* should be a list of lists of the form (*symbol macrofunction*) and *newenv* will contain local macro bindings for each *symbol* with *macrofunction* as its macroexpansion function. Each *macrofunction* is a function of two arguments, a form and an environment, which should return the expanded form.

*declare* should be a list of declaration-specifiers, which will be added to *newenv* as if by `declare`.

It is an error to use a symbol in *symbol-macro* that is also in *variable* or is declared special.

It is an error to use a symbol in *macro* that is also in *function*.

*newenv* has the same extent as *env*, that is it might have dynamic-extent within the function that created *env*.

The lists passed to `augment-environment` should be not destructively modified afterwards.

Notes      `augment-environment` is part of the environment access API which is based on that specified in *Common Lisp: the Language* (2nd Edition).

## **avoid-gc** *Function*

Summary     Avoids garbage collection if possible in 32-bit LispWorks.

Package     `hcl`

Signature    `avoid-gc => previous-results`

Arguments    None.

Values       The function returns the previous settings of `minimum-for-sweep`, `maximum-overflow` and `minimum-overflow`. (see `set-gc-parameters` for details of these.)

Description    `avoid-gc` sets various internal parameters so that garbage collection is avoided as far as possible.

This can be useful with non-interactive programs.

If you use `avoid-gc`, use `normal-gc` later to reset the parameters to their default settings.

Notes        `avoid-gc` is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations. In 64-bit implementations, you can use `set-`

**default-segment-size** to increase the default size of segments in the lower generations (typically generations 0 and 1). This will lead to less frequent garbage collections.

| Description | <p>The macro <code>block-promotion</code> executes <i>body</i> and prevents promotion of objects into generation 2 during this execution. After <i>body</i> is executed, generations 0 and 1 are collected.</p> <p>This is useful when a significant number of transient objects actually survive all the garbage collections on generation 1. These would normally then be promoted and, by default, never get collected. In such a situation, <code>(gc-generation t)</code> will free a large amount of space in generation 2.</p> <p><code>block-promotion</code> can be thought of as doing <code>set-promotion-count</code> on generation 1 with an infinite <i>count</i>, for the duration of <i>body</i>.</p> <p><code>block-promotion</code> is suitable only for use in particular operations that are known to create such relatively long-lived, but transient, objects. In typical uses these are objects that live for a few seconds to several hours. An example usage is Lisp-Works <code>compile-file</code>, to ensure the transient compile-time data gets collected.</p> <p><code>block-promotion</code> has global scope and hence may not be useful in an application such as a multi-threaded server. During the execution of <i>body</i>, generation 1 grows to accommodate all the allocated data, which may have some negative effects</p> |                                                          |

on the behavior of the system, in particular on its interactive response.

|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Used in a build script to determine if LispWorks is building an intermediate image when making a universal binary.                                                                                                                                                                                                                                                                                                                             |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Signature   | <code>building-universal-intermediate-p =&gt; intermediatep</code>                                                                                                                                                                                                                                                                                                                                                                             |
| Arguments   | None                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Values      | <code>intermediatep</code> A boolean.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description | <p>The function <code>building-universal-intermediate-p</code> can be used in a build script to determine if it is being executed to build one of the architectures of a universal binary.</p> <p>The return value <code>intermediatep</code> is <code>nil</code> in most cases. It will be <code>t</code> only when building an intermediate image for the purpose of building a universal binary, either by <code>save-universal-</code></p> |

`from-script` or the Application Builder (see the *LispWorks IDE User Guide*).

This is useful if there are some configuration that should be done only in a universal binary image but not in a mono-architecture ("thin") image. Whether the intermediate image will be the Intel or the PowerPC part of the universal binary can be determined by checking `*features*`.

On architectures that do not have universal binaries, this function always returns `nil`.

## **calls-who** *Function*

|             |                                                                                                                                                         |                        |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Summary     | Lists functions called by a function.                                                                                                                   |                        |
| Package     | <code>hcl</code>                                                                                                                                        |                        |
| Signature   | <code>calls-who dspec =&gt; callees</code>                                                                                                              |                        |
| Arguments   | <code>dspec</code>                                                                                                                                      | A <code>dspec</code> . |
| Values      | <code>callees</code>                                                                                                                                    | A list.                |
| Description | The function <code>calls-who</code> returns a list of the <code>dspecs</code> naming the functions called by the function named by <code>dspec</code> . |                        |
|             | See also the editor commands <code>List Callees</code> , and <code>Show Paths From</code> .                                                             |                        |
| Notes       | The cross-referencing information used by <code>calls-who</code> is generated when code is compiled with source-level debugging switched on.            |                        |
| Example     | <code>(calls-who '(method foo (string)))</code>                                                                                                         |                        |

## **cd** *Macro*

Summary      Changes the current directory.

Package      **hcl**

Signature      **cd &optional directory => current-dir**

Arguments      **directory**      A pathname designator specifying the new directory.

Values      **current-dir**      A physical pathname.

Description      The macro **cd** changes the current directory to that specified by **directory**. **directory** may be an absolute or relative pathname, and defaults to the string "**~/**".

**get-working-directory**

## **change-directory** *Function*

Summary      Changes the current directory.

Package      **hcl**

Signature      **change-directory directory => current-dir**

Arguments      **directory**      A pathname designator specifying the new directory.

Values      **current-dir**      A physical pathname.

|             |                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <code>change-directory</code> changes the current directory to that specified by <i>directory</i> . <i>directory</i> may be an absolute or relative pathname. |
|             | Use <code>get-working-directory</code> to find the current directory.                                                                                         |
| See also    | <code>cd</code><br><code>get-working-directory</code>                                                                                                         |

## check-fragmentation *Function*

|             |                                                                                                                                                                                                   |                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Provides information about the fragmentation in a generation in 32-bit LispWorks.                                                                                                                 |                                                                                                                                                             |
| Package     | <code>hcl</code>                                                                                                                                                                                  |                                                                                                                                                             |
| Signature   | <code>check-fragmentation gen-num =&gt; total-free, total-small-blocks, total-large-blocks</code>                                                                                                 |                                                                                                                                                             |
| Arguments   | <code>gen-num</code>                                                                                                                                                                              | 0 for the most recent generation, 1 for the most recent two generations, and so on up to a maximum (usually 3). Numbers outside this range signal an error. |
| Values      | <code>total-free</code>                                                                                                                                                                           | Total free space in the generation.                                                                                                                         |
|             | <code>total-small-blocks</code>                                                                                                                                                                   | Amount of free space in the generation which is available in blocks of 512 bytes or larger.                                                                 |
|             | <code>total-large-blocks</code>                                                                                                                                                                   | Amount of free space in the generation which is available in blocks of 4096 bytes or larger.                                                                |
| Description | The latter two values give indication of the level of fragmentation in the generation. This information can be used, for example, to decide whether to call <code>try-move-in-generation</code> . |                                                                                                                                                             |

|          |                                                                                                                                                                                                                                     |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>check-fragmentation</code> is implemented only in 32-bit Lisp-Works. It is not relevant to the Memory Management API in 64-bit implementations, where <code>gen-num-segments-fragmentation-state</code> is available instead. |

|             | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Frees memory and reduces the size of the image, if possible.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Signature   | <code>clean-down &amp;optional full =&gt; new-size</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Arguments   | <code>full</code> controls whether to operate on the highest generation. The default is <code>t</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Values      | <code>new-size</code> The new size of the image, after reduction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description | <p>Tries to free as much memory as possible and then reduce the size of the image as much as possible, and also move all the allocated objects to an old generation.</p> <p>If <code>full</code> is <code>t</code>, <code>clean-down</code> does a mark and sweep on generation 3, promotes all the objects into generation 3, deletes the empty segments and tries to reduce the image size. This is called by default before saving an image.</p> <p>If <code>full</code> is <code>nil</code>, <code>clean-down</code> does a mark and sweep on generation 2, promotes all the objects to generation 2 and tries to reduce the size of all generations up to 2, but does not touch generation 3.</p> <p><code>clean-down</code> may fail to delete empty segments if there are static segments in high address space.</p> |

|          |                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <ol style="list-style-type: none"> <li>1. <code>try-move-in-generation</code> uses less CPU than <code>clean-down</code>, though it does not do the mark and sweep.</li> <li>2. In 64-bit LispWorks, <code>clean-down</code> is implemented as if by <code>(gc-generation 7 :coalesce t)</code> though you can use <code>gc-generation</code> directly for better control.</li> </ol> |

## clean-generation-0 *Function*

|             |                                                                                                                                                                                                                                                                                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Attempts to promote all objects from generation zero into generation one, thereby clearing generation zero, in 32-bit LispWorks.                                                                                                                                                       |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                       |
| Signature   | <code>clean-generation-0 =&gt; 1</code>                                                                                                                                                                                                                                                |
| Arguments   | None                                                                                                                                                                                                                                                                                   |
| Values      | Returns the value 1.                                                                                                                                                                                                                                                                   |
| Description | This is useful when passing from a phase of creating long-lived data to a phase of mostly ephemeral data, for example, the end of loading an application and the start of its use.                                                                                                     |
| Notes       | <ol style="list-style-type: none"> <li>1. The function may not be very useful, as it may be more efficient to directly allocate the objects in a particular generation in the first place, using <code>allocation-in-gen-num</code> or <code>set-default-generation</code>.</li> </ol> |

2. `clean-generation-0` is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations, where the same effect can be obtained by a call (`gc-generation 0`).

Example      ; allocate lots of non-ephemeral objects  
               ; .....,  
               (clean-generation-0)

## collect-generation-2                                  Function

Summary      Controls whether generation 2 is garbage collected in 32-bit LispWorks.

Package      `hcl`

Signature     `collect-generation-2 on => size`

Arguments     `on`                                  If `on` is `nil`, generation 2 is not garbage collected. If `on` is `t`, the generation is garbage collected.

Values        `size`                                  The current size of the image.

Description     Controls whether generation 2 is garbage collected. (Generation 2 normally holds long-lived objects created dynamically.)

Notes         `collect-generation-2` is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in

64-bit implementations, where you can use `set-blocking-gen-num` instead.

|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <i>output-truename</i> A pathname or <code>nil</code> .<br><i>warnings-p</i> A generalized boolean.<br><i>failure-p</i> A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description | <p>The function <code>compile-file-if-needed</code> compares the <code>file-write-date</code> of the source file named by <i>input-pathname</i> with the <code>file-write-date</code> of the appropriate fasl file (as computed by <code>compile-file-pathname</code> from <i>input-pathname</i> and <i>output-file</i>).</p> <p>If the fasl file does not exist or is older than <i>input-pathname</i>, then <code>compile-file</code> is called with <i>input-pathname</i>, <i>output-file</i>, <i>load</i> and any other arguments passed., and the values returned are those returned from <code>compile-file</code>.</p> <p>Otherwise, if <i>load</i> is true <code>compile-file-if-needed</code> loads the fasl file and returns <code>nil</code>, and if <i>load</i> is <code>nil</code> it simply returns <code>nil</code>.</p> |

Example

```

CL-USER 19 > (compile-file-if-needed "H:/tmp/foo.lisp"
 :output-file
 "C:/temp/")
;; Compiling file H:/tmp/foo.lisp ...
;; Safety = 3, Speed = 1, Space = 1, Float = 1,
Interruptible = 0
;; Compilation speed = 1, Debug = 2, Fixnum safety = 3
;; Source level debugging is off
;; Source file recording is on
;; Cross referencing is off
; (TOP-LEVEL-FORM 1)
; (TOP-LEVEL-FORM 2)
; (TOP-LEVEL-FORM 3)
; FOO
; BAR
#P"C:/temp/foo.ofasl"
NIL
NIL

CL-USER 20 > (compile-file-if-needed "H:/tmp/foo.lisp"
 :output-file
 "C:/temp/"
 :load t)
; Loading fasl file C:\temp\foo.ofasl
NIL

|             | <i>executable-name</i>  | <code>t</code> or <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Values      | <i>path</i>             | A pathname.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description |                         | <p>The function <code>create-macos-application-bundle</code> creates a Mac OS X application bundle for the running LispWorks image, and returns the pathname <i>path</i> in which an image is expected to be saved. If you are saving an image, it is convenient to use <code>save-image-with-bundle</code>.</p> <p><i>target-path</i> is where the new bundle is created.</p> <p>By default <code>create-macos-application-bundle</code> uses the application bundle of the current image as a template, and modifies it according to its arguments. If you do not supply of any of the keyword arguments, the only modification is to the actual path.</p> <p><i>template-bundle</i> can be supplied to provide a path for an application bundle which will be used as a template. If <i>template-bundle</i> is not supplied, <code>create-macos-application-bundle</code> uses the path of the bundle of the current image. Except when specified, all the other parameters default to their values in the <i>template-bundle</i>.</p> <p><i>bundle-name</i> provides CFBundleName. The default value is the name of the last directory component in <i>target-path</i>.</p> <p><i>signature</i> is the signature in the PkgInfo file.</p> |

*version* is the version value, CFBundleVersion. If *template-bundle* is nil, *version* defaults to the value returned by `cl:lisp-implementation-version`.

*executable-name* is the filename of the LispWorks image executable, not including the directory. The default value of *executable-name* is the pathname name of the last component of *target-path*.

*package-type* is the package type, CFBundlePackageType. The default value of *package-type* is "APPL".

*extension* is the extension to add to the last component of *target-path*. The default value of *extension* is "app", as in "LispWorks.app".

The default value of *document-types* is `t`, which means copy them from *template-bundle*.

`create-macos-application-bundle` is implemented only in LispWorks for Macintosh.

## `create-temp-file`

## `open-temp-file`

## *Functions*

Summary      Creates a "temp file" and returns a pathname or a stream to it.

Package      `hcl`

Signature      `create-temp-file &key file-type directory prefix => pathname`

Signature      `open-temp-file &key file-type element-type directory prefix  
delete-when-close external-format => stream`

Arguments      `file-type`      A string or `nil`.

`element-type`      A type-specifier.

| Values      | <i>pathname</i>          | A pathname.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | <i>tream</i>             | An I/O stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description |                          | <p>The function <code>open-temp-file</code> opens a "temp file". This is a new file in the "temp directory" which is guaranteed to be new. Its name contains a random element. The permissions of the file are read-write for the user only.</p> <p><i>file-type</i> is the file type of the name. The default value of <i>file-type</i> is "tmp".</p> <p><i>directory</i>, if supplied, is the directory to create the file in. It defaults to the default temp directory, which is what <code>get-temp-directory</code> returns, which defaults to what the Operating System uses as the temp directory.</p> <p><i>prefix</i> is used as the first part of the file name. The default prefix is "<code>1wtemp_machinename_pid</code>". More characters are appended to make the name unique and random.</p> <p>If <i>delete-when-close</i> is non-nil, when the stream <i>stream</i> that is returned is closed, the system tries to delete the file quietly. That is, it tries to avoid giving an error if it fails.</p> <p><i>element-type</i> and <i>external-format</i> are interpreted the same way as in <code>open</code>.</p> <p>The stream that is returned is an I/O stream.</p> <p>The function <code>create-temp-file</code> creates a new temp file and returns the <i>pathname</i> for it. <code>create-temp-file</code> behaves exactly like <code>open-temp-file</code>, as described above, except that it returns a pathname rather than a stream to the new file.</p> |

- Notes
1. `pathname` can be called to find the pathname that was used in `open-temp-file`. The file can be guaranteed to be new only if the temp directory is configured correctly.
  2. The default "temp directory" can be found by using `get-temp-directory`.
  3. When `delete-when-close` is non-nil, it tries to delete the file when the stream is closed, but that does not necessarily succeed. On Microsoft Windows it certainly fails when the file is still opened (for example, by another stream in the same process or another process)

| Signature   | <code>create-universal-binary target-image src-image1 src-image2 =&gt; target-image</code>                                                           |                 |
| Arguments   | <code>target-image</code> A pathname designator.<br><code>src-image1</code> A pathname designator.<br><code>src-image2</code> A pathname designator. |                 |
| Values      | <code>target-image</code> A pathname designator.                                                                                                     |                 |
| Description | This function is intended for advanced use. See the function <code>save-universal-from-script</code> for a simpler way to create a universal binary. |                 |

The function `create-universal-binary` writes a universal binary to the file *target-image* from the saved image files *src-image1* and *src-image2*. The value of *target-image* is returned.

The source images *src-image1* and *src-image2* must both be LispWorks for Macintosh mono-architecture ("thin") images and one should be for the Intel architecture and the other for the PowerPC architecture (the order is immaterial). For example, they could have been created by `save-image` or `deliver`.

- Notes
1. The function `create-universal-binary` checks that *src-image1* and *src-image2* are LispWorks images of different architectures, but it does not check how they were saved or how similar they are. You need to ensure that both images contain the same functionality.
  2. The function `create-universal-binary` can only be called from a LispWorks for Macintosh image that is itself a universal binary, such as the distributed image.

- Example
- Suppose that you have saved two images, `my-application-intel` and `my-application-powerpc`, which contains the same application code loaded on an Intel Macintosh and a PowerPC Macintosh. The following command will combine them into a universal binary `my-application` that will run on both kinds of Macintosh:

```
(create-universal-binary "my-application"
 "my-application-intel"
 "my-application-powerpc")
```

| Package            | <code>hcl</code>                                                                                                                                               |
| Signature          | <code>current-stack-length =&gt; stack-size</code>                                                                                                             |
| Arguments          | None                                                                                                                                                           |
| Values             | <code>stack-size</code> The current size of the stack, in 32 bit words<br>(in 32-bit implementations) or 64-bit words<br>(in 64-bit implementations).          |
| Compatibility note | In LispWorks 4.4 and previous on Windows and Linux platforms, <code>current-stack-length</code> was not implemented. This is fixed in LispWorks 5.0 and later. |
| Example            | <code>(current-stack-length) =&gt; 16000</code>                                                                                                                |
| See also           | <code>extend-current-stack</code><br><code>*sg-default-size*</code>                                                                                            |

|             | <i>Function</i>                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Return information about the function bindings of a symbol in an environment.                                                                                 |
| Package     | <code>hcl</code>                                                                                                                                              |
| Signature   | <code>declaration-information decl-name &amp;optional env =&gt; info</code>                                                                                   |
| Arguments   | <code>decl-name</code> A declaration name<br><code>env</code> An environment or <code>nil</code>                                                              |
| Values      | <code>info</code> Information about <code>decl-name</code>                                                                                                    |
| Description | The function <code>declaration-information</code> returns information about the declarations for <code>decl-name</code> in the environment <code>env</code> . |

The following values for *decl-name* are supported:

**optimize**      The value of *info* is a list of lists of the form *(quality value)*, where *quality* is one of the optimization qualities specified by the Common Lisp standard and extensions to Lisp-Works (for example `float`). Each *value* is the corresponding value for that quality.

**declaration**      The value of *info* is a list of symbols that have been declared as declaration names, for example by use of  
`(declaim (declaration ...))`

There are currently no other supported values for *decl-name*.

**Notes**      `declaration-information` is part of the environment access API which is based on that specified in *Common Lisp: the Language* (2nd Edition).

## \*default-package-use-list\*                          *Variable*

**Summary**      List of packages that newly created packages use by default.

**Package**      `hcl`

**Initial Value**      `("CL" "LW" "HCL")`

**Description**      This variable is the default value of the `:use` keyword to `defpackage`, which specifies which existing packages the package being defined inherits from.

**\*default-profiler-collapse\*** *Variable*

Summary      Controls collapsing of the profile tree.

Package      `hcl`

Initial Value      `nil`

Description      The variable `*default-profiler-collapse*` is a boolean indicating whether the profile tree should collapse functions with only one child function. The default value is `nil`.

See also      `print-profile-list`  
`set-up-profiler`

**\*default-profiler-cutoff\*** *Variable*

Summary      The minimum percentage that the profiler will display in the output tree.

Package      `hcl`

Initial Value      `0`

Description      The variable `*default-profiler-cutoff*` is the minimum percentage (0 to 100) that the profiler will display in its output tree. Functions below this percentage will not be displayed. The initial value is 0, meaning display everything.

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | The maximum number of lines of output that are printed during profiling.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Package       | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Initial Value | <code>100,000,000</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Description   | <p><code>*default-profiler-limit*</code> is the maximum number of lines of output in profile results. The default value is large to ensure that you receive all possible output requested.</p> <p><code>*default-profiler-limit*</code> only counts output lines for functions that are actually called during profiling. Therefore, if <code>*default-profiler-limit*</code> is 19, and 20 functions were profiled, you would receive full output if one or more of the functions were not actually called during profiling.</p> |
| See also      | <code>print-profile-list</code><br><code>set-up-profiler</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**\*default-profiler-sort\*** *Variable*

|               |                                                                                                                                                                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | The default sorting style for the profiler.                                                                                                                                                                                           |
| Package       | <code>hcl</code>                                                                                                                                                                                                                      |
| Initial Value | <code>:profile</code>                                                                                                                                                                                                                 |
| Description   | <p>The variable <code>*default-profiler-limit*</code> controls which column of the profiler's columnar report is used for sorting.</p> <p>The value can be one of <code>:profile</code>, <code>:call</code> or <code>:top</code>.</p> |
| See also      | <code>print-profile-list</code><br><code>set-up-profiler</code>                                                                                                                                                                       |

## **defglobal-parameter** *Function*

|             |                                                                                                                                                                                    |                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| Summary     | Defines a <code>hcl:special-global</code> parameter.                                                                                                                               |                |
| Package     | <code>hcl</code>                                                                                                                                                                   |                |
| Signature   | <code>defglobal-parameter name initial-value &amp;optional doc =&gt; name</code>                                                                                                   |                |
| Arguments   | <i>name</i>                                                                                                                                                                        | A symbol.      |
|             | <i>initial-value</i>                                                                                                                                                               | A Lisp object. |
|             | <i>doc</i>                                                                                                                                                                         | A string.      |
| Values      | <i>name</i>                                                                                                                                                                        | A symbol.      |
| Description | The macro <code>defglobal-parameter</code> has the same semantics as <code>cl:defparameter</code> , but also declares the name <i>name</i> to be <code>hcl:special-global</code> . |                |
| See also    | <code>defglobal-variable</code>                                                                                                                                                    |                |

| Summary   | Defines a <code>hcl:special-global</code> variable.                             |                |
| Package   | <code>hcl</code>                                                                |                |
| Signature | <code>defglobal-variable name &amp;optional initial-value doc =&gt; name</code> |                |
| Arguments | <i>name</i>                                                                     | A symbol.      |
|           | <i>initial-value</i>                                                            | A Lisp object. |
|           | <i>doc</i>                                                                      | A string.      |
| Values    | <i>name</i>                                                                     | A symbol.      |

|             |                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | The macro <b>defglobal-variable</b> has the same semantics as <b>cl:defvar</b> , but also declares the name <i>name</i> to be <b>hcl:special-global</b> . |
| See also    | <b>defglobal-parameter</b>                                                                                                                                |

## **delete-advice** *Macro*

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | Removes a piece of advice.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Package   | <b>hcl</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Signature | <pre><b>delete-advice</b> <i>dspec</i> <i>name</i> =&gt; <b>nil</b></pre> <p><i>dspec</i> ::= <i>fn-name</i>   <i>macro-name</i>  <br/> <i>(clos::method generic-fn-name [ (class*) ])</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Arguments | <p><b>dspec</b>      Specifies the functional definition to which the piece of advice belongs. The specification contains the name of the associated function. In the case of a method the list of classes is used to identify from which particular method the advice should come. This list must correspond exactly with the classes corresponding to the specialized parameters for some method belonging to the generic function.</p> <p><b>name</b>      A symbol naming the piece of advice to be removed. Since several pieces of advice may be attached to a single functional definition, the name is necessary to indicate which one is to be removed.</p> |
| Values    | <b>delete-advice</b> returns <b>nil</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <code>delete-advice</code> is used to remove a piece of advice. Advice is a way of altering the behavior of functions. Pieces of advice are associated with a function using <code>defadvice</code> . They define additional actions to be performed when the function is invoked, or alternative code to be performed instead of the function, which may or may not access the original definition. As well as being attached to ordinary functions, advice may be attached to methods and to macros (in this case it is in fact associated with the macro's expansion function). |
|             | <code>remove-advice</code> is a function, identical in effect to <code>delete-advice</code> , except that you need to quote the arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Notes       | <code>delete-advice</code> is an extension to Common Lisp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Package                | <code>hcl</code>                                                                                                                                                                                                                                                                                            |                 |
| Initial Value          | <code>nil</code>                                                                                                                                                                                                                                                                                            |                 |
| Description            | <code>*disable-trace*</code> controls tracing without affecting the tracing state. If it is set to <code>t</code> then tracing is switched off, but this does not call <code>untrace</code> . When the value of <code>*disable-trace*</code> is restored to <code>nil</code> , tracing continues as before. |                 |
| Notes                  | <code>*disable-trace*</code> is an extension to Common Lisp.                                                                                                                                                                                                                                                |                 |

| <i>func-and-args</i>     | A function designator or a list ( <b>function-designator . args</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                   |            |                  |                                                                                                    |                        |            |                          |            |              |                                        |                 |                        |                  |                                       |                      |                                                                        |              |                        |               |                   |
| <i>print</i>             | A generalized boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                   |            |                  |                                                                                                    |                        |            |                          |            |              |                                        |                 |                        |                  |                                       |                      |                                                                        |              |                        |               |                   |
| <i>stream</i>            | An output stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                   |            |                  |                                                                                                    |                        |            |                          |            |              |                                        |                 |                        |                  |                                       |                      |                                                                        |              |                        |               |                   |
| Description              | <p>The function <b>do-profiling</b> is a convenience function for profiling multiple threads, combining <b>start-profiling</b> and <b>stop-profiling</b>.</p> <p>The behavior of <b>do-profiling</b> with no arguments is the same as:</p> <pre>(progn   (start-profiling :processes :all)   (sleep 6)   (stop-profiling))</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                   |            |                  |                                                                                                    |                        |            |                          |            |              |                                        |                 |                        |                  |                                       |                      |                                                                        |              |                        |               |                   |

The arguments *initialize*, *processes*, *profile-waiting* and *ignore-in-foreign* are passed to `start-profiling`. They have the same default values as for `start-profiling`, except *processes* which defaults to `:all`.

The arguments *print* and *stream* are passed to `stop-profiling`. They have the same default values as in `stop-profiling`.

*sleep* is the time to sleep in seconds. If *sleep* is `nil` or 0 `do-profiling` does not sleep. Also, if *sleep* is supplied and either *function* or *func-and-args* are passed, it does not sleep.

*func-and-args*, and *function* together with *arguments*, can both be used for calling a function you supply. *func-and-args* is either a list of the form `(function-designator . args)`, in which case *function-designator* is applied to the *args*, or it is a function designator which is called without arguments. *function* is applied to *arguments*.

The order of execution is first *func-and-args* (if this is non-nil), then *function* together with *arguments* if *function* is non-nil, and then sleep if *sleep* was passed explicitly or both *function* and *func-and-args* are `nil`.

Example To profile whatever happens in the next 6 seconds:

```
(hcl:do-profiling)
```

To profile whatever happens in the next 10 minutes:

```
(hcl:do-profiling :sleep 600)
```

To run 4 processes in parallel with the same function and profile until they all die:

```
(defun check-all-processes-died (processes)
 (dolist (p processes t)
 (when (mp:process-alive-p p)
 (return nil)))

 (let ((processes
 (loop for x below 4
 collect
 (mp:process-run-function
 (format nil "my process ~a" x)
 () 'my-function))))
 (hcl:do-profiling
 :func-and-args
 (list 'mp:process-wait
 "Waiting for processes to finish"
 'check-all-process-died
 processes)))
```

## **dump-form** *Function*

Summary      Dumps selected forms to a stream.

Package      **hcl**

Signature      **dump-form form stream => nil**

Arguments      *form*      Form to be dumped.

*stream*      Stream form is to be dumped to.

Values      Returns **nil**.

Description      **dump-form** is used in conjunction with **with-output-to-fasl-file** to dump selected forms. A dumped form is evaluated when loaded using **load-data-file**.

See **with-output-to-fasl-file** for more details.

| Arguments   | <i>pathname</i> Name of the fasl file to be created.<br><i>forms</i> Forms to be dumped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Values      | Returns <b>nil</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Description | <p><b>dump-forms-to-file</b> dumps specified forms to a fasl file. Use the Common Lisp functions <b>make-load-form</b> and <b>make-load-form-saving-slots</b> to control the dumping of forms.</p> <p>To be able to load the output file, it must have a file type that LispWorks recognizes as a binary file. You can do it by:</p> <ul style="list-style-type: none"><li>• using the default binary file type, either by using the value of <b>*binary-file-type*</b> or <b>compile-file-pathname</b> as in the example below.</li><li>• using another file type, which you add to <b>*binary-file-types*</b>.</li></ul> <p>If the file <i>pathname</i> already exists, it is superseded.</p> <p>A fasl file created using <b>dump-forms-to-file</b> must be loaded only by <b>load-data-file</b>, and not by <b>load</b>.</p> |
| Example     | (defclass my-class () ((a :initarg :a :accessor my-a)))                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

```
(defmethod make-load-form ((self my-class) &optional
 environment)
 (declare (ignore environment))
 `(make-instance ',(class-name (class-of self))
 :a ',(my-a self)))

 (setq *my-instance* (make-instance 'my-class :a 42))

 (dump-forms-to-file
 (compile-file-pathname "my-instance")
 (list `(*my-instance* ,*my-instance*)))
```

In another session, with the same definition of `my-class`, loading the file "`my-instance`" using `load-data-file` will create an equivalent instance of `my-class`:

```
(sys:load-data-file
 (compile-file-pathname "my-instance"))
```

## enlarge-generation

### *Function*

|             |                                                                                                                                                       |                                                                  |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| Summary     | Enlarges a generation in 32-bit LispWorks.                                                                                                            |                                                                  |
| Package     | <code>hcl</code>                                                                                                                                      |                                                                  |
| Signature   | <code>enlarge-generation gen-num size =&gt; result</code>                                                                                             |                                                                  |
| Arguments   | <code>gen-num</code>                                                                                                                                  | A generation number.                                             |
|             | <code>size</code>                                                                                                                                     | The amount (in bytes) by which the generation is to be enlarged. |
| Values      | <code>result</code>                                                                                                                                   | A boolean.                                                       |
| Description | The function <code>enlarge-generation</code> enlarges generation <code>gen-num</code> by <code>size</code> bytes. If possible, an existing segment in |                                                                  |

generation *gen-num* is enlarged, otherwise a new segment of size *size* is added to the generation.

*result* is `t` on success and `nil` on failure.

This function is useful when it is known that a generation will need to grow. After `enlarge-generation` is called, the garbage collector is saved the work of deducing that the generation must grow.

`enlarge-generation` is most useful in non-interactive applications, where relatively long GC delays are not a problem. In this case, enlarging generations 0 and 1 by several Mb may improve the overall performance of the GC.

|          |                                                                                                                                                                                                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>enlarge-generation</code> is implemented only in 32-bit Lisp-Works. It is not relevant to the Memory Management API in 64-bit implementations. In 64-bit implementations you can use <code>set-default-segment-size</code> . |
| See also | <code>set-default-segment-size</code>                                                                                                                                                                                              |

## **enlarge-static** *Function*

|             |                                                                                                                                                                           |                                      |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| Summary     | Enlarges the size of the first static segment in 32-bit LispWorks.                                                                                                        |                                      |
| Package     | <code>hcl</code>                                                                                                                                                          |                                      |
| Signature   | <code>enlarge-static size =&gt; result</code>                                                                                                                             |                                      |
| Arguments   | <code>size</code>                                                                                                                                                         | A non-negative <code>fixnum</code> . |
| Values      | <code>result</code>                                                                                                                                                       | A boolean.                           |
| Description | This function can be used when the system would otherwise allocate additional static segments. Such additional segments would cause the application to grow irreversibly. |                                      |

*size* is the amount (in bytes) by which the static segment is to be enlarged. It is rounded up to a multiple of 64K.

*result* is `t` if the static segment was successfully enlarged, and `nil` otherwise.

Use `room`, with argument `t`, to find the size of the static segments, and thus the size by which to enlarge the first static segment.

Notes      `enlarge-static` is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations, where the irreversible growth problem described above does not exist.

## **expand-generation-1** *Function*

Summary     Controls expansion of generation 1 in 32-bit LispWorks.

Package     `hcl`

Signature    `expand-generation-1 on`

Arguments    `on`                `t, nil` or `1`.

Description    The function `expand-generation-1` controls the subsequent behavior of the garbage collector when insufficient space is freed by a `mark-and-sweep`. When this occurs, either generation 1 is expanded, or the objects in it are promoted.

If `on` is `nil`, generation 1 is never expanded.

If *on* is `t`, generation 1 is always expanded (rather than promotion) when needed.

If *on* is `1`, generation 1 is only expanded if its current size is less than 500000 bytes. This is the initial setting.

|          |                                                                                                                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>expand-generation-1</code> is implemented only in 32-bit Lisp-Works. It is not relevant to the Memory Management API in 64-bit implementations, where you can use <code>set-default-segment-size</code> .           |

## extend-current-stack

## Function

|                    |                                                                                                                                                               |                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| Summary            | Extends the current stack.                                                                                                                                    |                                                                     |
| Package            | <code>hcl</code>                                                                                                                                              |                                                                     |
| Signature          | <code>extend-current-stack &amp;optional how-much =&gt; size</code>                                                                                           |                                                                     |
| Arguments          | <i>how-much</i>                                                                                                                                               | What percentage the stack should be extended by. The default is 50. |
| Values             | <i>size</i>                                                                                                                                                   | The new size of the stack, after extending.                         |
| Description        | Extend the current stack by the given percentage.                                                                                                             |                                                                     |
| Compatibility note | In LispWorks 4.4 and previous on Windows and Linux platforms, <code>extend-current-stack</code> is not implemented. This is fixed in LispWorks 5.0 and later. |                                                                     |

Example      To double the size of the current stack:

```
(hcl:extend-current-stack 100)
```

See also      **current-stack-length**  
**\*stack-overflow-behaviour\***

## **extended-time** *Macro*

Summary      Prints useful timing information, including information on garbage collection (GC) activity.

Package      **hcl**

Signature      **extended-time &body body**

Arguments      **body**                  The forms to be timed.

Description      The macro **extended-time** runs the forms in *body*. It then prints a summary of the time taken followed by a breakdown of time spent in the GC.

The three columns of the GC breakdown show, respectively, total time, user time, and system time. The rows of the GC breakdown indicate the type of activity.

In 32-bit LispWorks these rows begin:

**main promote** indicates promotions from generation 0.

**internal promote**

indicates when an attempt to promote from one generation to the next causes promotion of the higher generation, to make room for the objects from the lower generation.

**fixup**                  is a part of the compaction and promotion process.

In 64-bit LispWorks these rows begin:

**Standard *gen-num* (*n* calls)**

indicates *n* Standard GCs (includes automatic GCs and calls to `gc-generation`) in which the highest generation collected was *gen-num*.

**Marking *gen-num* (*n* calls)**

indicates *n* Marking GCs (includes calls to `marking-gc`) in which the highest generation collected was *gen-num*.

Thus in the example below

```
Standard 1 (1 calls) ...
```

indicates that there was 1 Standard GC in which the highest generation collected was 1.

Example

This example illustrates output in 32-bit LispWorks:

```
CL-USER 57 > (extended-time (foo))
Timing the evaluation of (PROGN (FOO))

User time = 26.703
System time = 0.109
Elapsed time = 27.047
Allocation = 40021902832 bytes
0 Page faults

 total / user
/ system
total gc activity = 3.312500 /
3.312500 / 0.000000
main promote (1 calls) = 0.000000 /
0.000000 / 0.000000
mark and sweep (7305 calls) = 3.312500 /
3.312500 / 0.000000
internal promote (0 calls) = 0.000000 /
0.000000 / 0.000000
promote (0 calls) = 0.000000 /
0.000000 / 0.000000
fixup (1 calls) = 0.000000 /
0.000000 / 0.000000
compact (0 calls) = 0.000000 /
0.000000 / 0.000000
10006387712
0.0
```

This example illustrates output in 64-bit LispWorks:

```

CL-USER 3 > (extended-time (foo))
Timing the evaluation of (PROGN (FOO))

User time = 11.433
System time = 0.268
Elapsed time = 11.197
Allocation = 80040251696 bytes
5 Page faults

 total / user /
system
total gc activity = 2.168062 / 2.126444
/ 0.041618
Standard 0 (28545 calls) = 2.153886 / 2.119799
/ 0.034087
Standard 1 (1 calls) = 0.014176 / 0.006645
/ 0.007531
10006387712
0.0

```

| <i>external-format</i> | An external format specification, default value <code>:default</code> .                                                                                                                                                                                                                                                                                                      |             |                                                        |               |                                                                                  |                        |                                                                         |
| Values                 | <i>string</i> A string containing characters from <i>file</i> .                                                                                                                                                                                                                                                                                                              |             |                                                        |               |                                                                                  |                        |                                                                         |

|             |                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Description | Returns the entire contents of <i>file</i> (if <i>length</i> is <code>nil</code> ), or the first <i>length</i> characters, as a string. |
| Example     | <pre>CL-USER 26 &gt; file-string "configure.lisp" :length 18 ";; -*- Mode: Lisp;"</pre>                                                 |
| See also    | <code>guess-external-format</code>                                                                                                      |

## **file-writable-p** *Function*

|             |                                                                                                                                                                                                                                               |                                                        |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| Summary     | Tests whether a file is writable.                                                                                                                                                                                                             |                                                        |
| Package     | <code>hcl</code>                                                                                                                                                                                                                              |                                                        |
| Signature   | <code>file-writable-p <i>file</i> =&gt; <i>result</i></code>                                                                                                                                                                                  |                                                        |
| Arguments   | <code>file</code>                                                                                                                                                                                                                             | A pathname, string or file-stream, designating a file. |
| Values      | <code>result</code>                                                                                                                                                                                                                           | <code>t</code> or <code>nil</code>                     |
| Description | Checks if <i>file</i> is writable. Note that this checks the properties of the file, so trying to write to the file may still fail if the file is non-writable for other reasons, for example if it is opened for writing by another program. |                                                        |
| Example     | <pre>CL-USER 44 &gt; file-writable-p (sys:lispworks-file "private-patches/load.lisp") T</pre>                                                                                                                                                 |                                                        |

## **find-object-size** *Function*

|         |                                                                     |
|---------|---------------------------------------------------------------------|
| Summary | Returns the size in bytes of the representation of any Lisp object. |
| Package | <code>hcl</code>                                                    |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signature   | <code>find-object-size <i>object</i> =&gt; <i>size</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Arguments   | <i>object</i> Any Common Lisp form.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Values      | <p>The result is an integer which is the number of bytes of heap storage currently used to represent the object. If the object takes up no heap storage (fixnum or character), then 0 is returned. Such objects are represented by an immediate value held in a single machine “word”.</p> <p>The size of a heap object includes hidden space required to hold type and other information; for instance, a base-string of 10 1-byte characters occupies more than 10 bytes of storage.</p> |
| Description | Certain Common Lisp objects are not represented by a single heap object; for instance, using <code>find-object-size</code> on a hash-table is misleading as the function returns the size of the hash-table descriptor, rather than the total of the descriptor and the hash-table-array. General vectors and arrays also have this property. All symbols are of the same size, since the print name is not part of a symbol object.                                                       |
| Example     | <pre>(hcl:find-object-size   (make-string 1000 :initial-element #\A                :element-type 'base-char)) =&gt; 1012</pre>                                                                                                                                                                                                                                                                                                                                                             |

| Description | <p>The function <code>finish-heavy-allocation</code> tells the system that the application finished doing 'heavy' allocation, and from that point onwards allocation is 'normal'. The main distinction between heavy and normal allocation is the typical lifetime of objects: normal allocation means most of new objects are ephemeral, while heavy allocation a large proportion of the new objects are long-lived.</p> <p>Heavy allocation normally happens when loading, either the application itself or large amount of data. Operations that do not involve loading will almost always be normal. Hence the time that is useful to call <code>finish-heavy-allocation</code> is after loading something.</p> |

## flag-special-free-action *Function*

**Summary** Flags an object for special action on garbage collection.

## Package hcl

Signature      **flag-special-free-action** *object*    => t

**Arguments**      *object*      The object on which the special actions are to be performed. This cannot be a symbol.

## Values      Returns t.

**Description** Note that all the current special-free-action functions are performed on the object. Use `flag-not-special-free-action` to unflag an object.

```
Example CL-USER 29 > (make-instance 'capi:title-pane)
 #<CAPI:TITLE-PANE "" 20F9898C>

 CL-USER 30 > (flag-special-free-action *)
T
```

## function-information      *Function*

**Summary**      Return information about the function bindings of a symbol in an environment.

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                  |                                                                         |                     |                                                                    |                        |                                                                       |                            |                                                                               |

| Description | <p>The function <code>gc-generation</code> does a Garbage Collection of a specific generation. The actual operation is different between 64-bit LispWorks and 32-bit LispWorks.</p> <p><i>gen-num</i> should be a valid generation number, or <code>t</code>. The value <code>t</code> is mapped to the blocking generation number in 64-bit LispWorks, and to <code>2</code> in 32-bit LispWorks. For backwards compatibility the keyword <code>:blocking-gen-num</code> is also accepted, with the same meaning as <code>t</code>.</p> <p>It is especially helpful to GC the blocking generation (or other higher generations) when large, long-lived data structures become garbage. This is because higher generations are rarely collected by default. For the higher generations, the GC takes longer but recovers more space.</p> <p>Another situation which may require <code>gc-generation</code> is when objects are marked for special free action (by <code>flag-special-free-action</code> or <code>free-function</code> in a weak hash table). If such objects live long enough to be promoted to higher generation, they may not be GCed long after there are no pointers to them. If the free action is important, you may need to periodically GC higher generation (typically the blocking generation, by passing <i>gen-num t</i>).</p> <p><b><u>Operation in 64-bit LispWorks</u></b></p> <p>By default <code>gc-generation</code> operates on the live objects in generation <i>gen-num</i> and all lower generations at or above the generation specified by <i>block</i> by copying them inside their current generation, and it operates on the live objects in generations lower than <i>block</i> by copying them to the next higher generation.</p> <p>If <i>promote</i> is non-nil, the live objects in generation <i>gen-num</i> are also promoted to the next generation. That is the same opera-</p> |                                                                            |

tion that happens when the GC is invoked automatically. The default value of *promote* is `nil`.

If *coalesce* is non-`nil`, all non-static live objects in lower generations are promoted to generation *gen-num*. That is what `clean-down` does (with *gen-num* being the highest generation). It may be useful directly in some cases. The default value of *coalesce* is `nil`.

*block* specifies a generation number up to which to promote. An integer value specifies the generation number. If *block* is `:blocking-gen-num`, then `gc-generation` promotes up to the blocking generation. If *block* is `:all`, then `gc-generation` promotes nothing. The default value of *block* is `:blocking-gen-num`.

`gc-generation` is useful when you know points in your application where many objects tend to die, or when you know that that application is less heavily loaded at some time. Typically many objects die in the end (or beginning) of an iteration in a top level loop of the application, and that is normally a useful place to put a call to `gc-generation` of generation 2 or generation 3. If you know a time when the application can spend time GCing, a call to `gc-generation` with a higher value of *gen-num* may be useful. It is probably never really useful to use `gc-generation` on generation 0 or 1.

To decide on which *gen-num* to call `gc-generation`, check which generation gets full by making periodic calls to `rroom`.

`gc-generation` with *promote* or *coalesce* may also be useful to move objects from the blocking generation to higher generations, which does not happen automatically (except when saving the image). For example, after loading a large amount of code, and before generating any data that may die shortly, assuming the blocking generation is 3, it may be useful to do:

```
(gc-generation 4 :coalesce t)
```

to move all (non-static) objects to generation 4, where they will not be touched by the GC any more (except following pointers to younger generations).

### Operation in 32-bit LispWorks

**gc-generation** marks and sweeps the generation *gen-num* and all generations below, and then does some additional cleanups. *coalesce*, *promote* and *block* are ignored.

Compatibility note In 32-bit LispWorks, **gc-generation** simply calls **mark-and-sweep**. This has a similar effect, but two significant differences must be noted:

1. by default, **gc-generation** promotes the young generations, so repeated calls to **gc-generation** will promote everything to generation *gen-num* or generation *block* (whichever is lower). In contrast **mark-and-sweep** never promotes.
2. In 32-bit LispWorks, generation 2 is the blocking generation. In 64-bit LispWorks, the default blocking generation is generation 3. That is because the 64-bit implementation promotes faster and so needs more generations before the block.

Also note that

```
(gc-generation t)
```

is intended as the replacement of

```
(mark-and-sweep 2)
```

| Summary     | Garbage collects if the previous call requires more space than is actually available in 32-bit LispWorks.                                                                                                                                                                                                                                                                                                                                                                  |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Signature   | <code>gc-if-needed =&gt; nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Arguments   | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Values      | Returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Description | This function checks to see if the amount of allocation from the previous call is more than <code>system:*allocation-interval*</code> , and if it is, performs a mark and sweep and promotion on generation 0. It also tries to reduce the big-chunk area. This is a fairly brief operation, and can be used whenever some operation is finished and may have left some garbage. The system itself uses it after compiling and loading files, when waiting for input, etc. |
| Notes       | <code>gc-if-needed</code> does nothing in 64-bit LispWorks.                                                                                                                                                                                                                                                                                                                                                                                                                |

|--------------------------|--------------------------------------------------------|-----------------------------------------------------------------------------------------|
| Summary                  |                                                        | Returns the current values of various garbage collector parameters in 32-bit LispWorks. |
| Package                  | <code>hcl</code>                                       |                                                                                         |
| Signature                | <code>get-gc-parameters parameters =&gt; values</code> |                                                                                         |
| Arguments                | <code>parameters</code>                                | A keyword representing a single GC parameter. Any other value means all parameters.     |

|             |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <i>values</i> | If <i>parameters</i> specifies a single GC parameter, the value of that parameter is returned. Otherwise <i>values</i> is an alist containing every GC parameter, together with its current value.                                                                                                                                                                                                                                                                 |
| Description |               | See <code>set-gc-parameters</code> for a full description of these parameters.<br>With keyword argument, of one of the parameters, the corresponding value is returned.                                                                                                                                                                                                                                                                                            |
| Notes       |               | <code>get-gc-parameters</code> is implemented only in 32-bit Lisp-Works. It is not relevant to the Memory Management API in 64-bit implementations.                                                                                                                                                                                                                                                                                                                |
| Example     |               | <pre>CL-USER 1 &gt; (get-gc-parameters :minimum-overflow) 500000  CL-USER 2 &gt; (pprint (get-gc-parameters t))  ((:ENLARGE-BY-SEGMENTS . 10)  (:MINIMUM-FOR-PROMOTE . 1000)  (:MAXIMUM-OVERFLOW . 1000000)  (:MINIMUM-OVERFLOW . 500000)  (:MINIMUM-BUFFER-SIZE . 200)  (:NEW-GENERATION-SIZE . 262144)  (:PROMOTE-MAX-BUFFER . 100000)  (:PROMOTE-MIN-BUFFER . 200)  (:MAXIMUM-BUFFER-SIZE . 131072)  (:MINIMUM-FOR-SWEEP . 8000)  (:BIG-OBJECT . 131072))</pre> |

|         |  | <i>Function</i>                                           |
|---------|--|-----------------------------------------------------------|
| Summary |  | Returns a directory that can be used for temporary files. |
| Package |  | <code>hcl</code>                                          |

|             |                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signature   | <code>get-temp-directory =&gt; directory</code>                                                                                                                                          |
| Values      | <code>directory</code> A pathname                                                                                                                                                        |
| Description | The function <code>get-temp-directory</code> returns a directory which is likely to be writable and can be used for temporary files.                                                     |
| Notes       | By default, the functions <code>create-temp-file</code> and <code>open-temp-file</code> use the result of <code>get-temp-directory</code> as the directory to create their temp file in. |
| See also    | <code>create-temp-file</code><br><code>example-compile-file</code><br><code>open-temp-file</code>                                                                                        |

## get-working-directory *Function*

|             |                                                                                                                                                        |                                               |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| Summary     | Finds the current working directory.                                                                                                                   |                                               |
| Package     | <code>hcl</code>                                                                                                                                       |                                               |
| Signature   | <code>get-working-directory =&gt; cwd</code>                                                                                                           |                                               |
| Arguments   | None.                                                                                                                                                  |                                               |
| Values      | <code>cwd</code>                                                                                                                                       | The current working directory, as a pathname. |
| Description | This function is used to find the current working directory. It returns a pathname, the directory component of which is the current working directory. |                                               |
| Example     | <pre>CL-USER 1 &gt; (get-working-directory) #P"/u/dubya/"</pre>                                                                                        |                                               |

|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary       | Controls LispWorks' response when <code>defpackage</code> is used on an existing package that is different from the definition given.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Package       | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Initial value | <code>(:warn :modify)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description   | <p>The standard explicitly declines to define what <code>defpackage</code> does if the named package already exists and is in a different state to that described by the <code>defpackage</code> form. The variable <code>*handle-existing-defpackage*</code> is an extension to Common Lisp which allows you to select between alternative behaviors that are known to be useful.</p> <p>The two alternatives are to modify the package to conform exactly to the definition, removing features if necessary, or to merely add features specified in the <code>defpackage</code> but missing from the package. You can also control whether a condition is signalled.</p> |

The variable consists of a list of any of the following:

|                 |                                                                           |
|-----------------|---------------------------------------------------------------------------|
| <b>:error</b>   | Signal an error.                                                          |
| <b>:warn</b>    | Signal a warning.                                                         |
| <b>:add</b>     | Add the new symbols to the externals, imports, and so on.                 |
| <b>:modify</b>  | Modify the package to have only these externals.                          |
| <b>:verbose</b> | The signalled errors or warnings also contain details of the differences. |

The options `:error` and `:warn` cannot be specified at the same time. One of `:add` and `:modify` must be specified. Undistinguished internals (that is, internal symbols that are not imported or shadowed), `:intern` options and sizes are ignored when deciding whether to signal.

Note that when you use `:modify` some symbols can be uninterned if `defpackage` imports another symbol with the same name from another package through `:import-from`, `:shadowing-import-from` or `:export`. This happens whether the symbol has a definition as a function, a variable, or nay other Lisp construct, so after making such a change in the package, you should re-execute the definitions that were (presumably erroneously) attached to the uninterned symbols.

Notes      `*handle-existing-defpackage*` is an extension to Common Lisp.

## **`*handle-old-in-package*`** *Variable*

Summary     Controls the handling of CLtL1-style `in-package` forms.

Package     `hcl`

Initial Value    `:warn`

Description    The variable `*handle-old-in-package*` controls what happens when a CLtL1-style `in-package` form is processed. This refers to the specification in Common Lisp the Language, first Edition, which preceded ANSI Common Lisp and specified `in-package` as a function with keyword arguments.

The allowed values are as follows:

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| <code>:quiet</code> | Quietly use the CLtL1 definition of the <code>in-package</code> function. |
|---------------------|---------------------------------------------------------------------------|

|                     |                                              |
|---------------------|----------------------------------------------|
| <code>:warn</code>  | Signal a warning and use the old definition. |
| <code>:error</code> | Signal a continuable error.                  |

See also `*handle-old-in-package-used-as-make-package*`

## **\*handle-old-in-package-used-as-make-package\*** *Variable*

Summary Controls the handling of CLtL1-style `in-package` forms.

Package `hcl`

Initial Value `:quiet`

Description The variable `*handle-old-in-package-used-as-make-package*` controls what happens when a CLtL1-style `in-package` form which attempts to create a package is processed. This refers to the specification in Common Lisp the Language, first Edition, which preceded ANSI Common Lisp and specified `in-package` as a function with keyword arguments.

The allowed values are as follows:

|                     |                                                                         |
|---------------------|-------------------------------------------------------------------------|
| <code>:quiet</code> | Handle according to the value of <code>*handle-old-in-package*</code> . |
| <code>:warn</code>  | Signal a warning and create the package.                                |
| <code>:error</code> | Signal a continuable error.                                             |

## **hash-table-weak-kind** *Function*

Summary Returns the weak kind of a hash table.

Signature `hash-table-weak-kind hash-table => weakness-state`

|             |                       |                                                                                                                                                                                                                                               |
|-------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments   | <i>hash-table</i>     | A hash table.                                                                                                                                                                                                                                 |
| Values      | <i>weakness-state</i> | A keyword or <code>nil</code> .                                                                                                                                                                                                               |
| Description |                       | The function <code>hash-table-weak-kind</code> returns the weak kind (or weakness state) of the hash table <i>hash-table</i> .<br><br>See <code>set-hash-table-weak</code> for the meaning of the different values of <i>weakness-state</i> . |
| See also    |                       | <code>set-hash-table-weak</code><br><code>make-hash-table</code>                                                                                                                                                                              |

## \*load-fasl-or-lisp-file\*

*Variable*

|             |                                                                                                                                                                                                                                                                                                                  |                                                                                                         |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Summary     | Controls the behavior of <code>load</code> for untyped pathnames.                                                                                                                                                                                                                                                |                                                                                                         |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                 |                                                                                                         |
| Description | The variable <code>*load-fasl-or-lisp-file*</code> determines whether <code>(load "foo")</code> should load the binary file ( <code>foo.ofasl</code> , <code>foo.ufasl</code> , <code>foo.xfasl</code> etc, depending on platform) or <code>foo.lisp</code> , when both exist. It may take the following values: |                                                                                                         |
|             | <code>:load-newer</code>                                                                                                                                                                                                                                                                                         | If the fasl is out-of-date, the lisp file is loaded, and a warning message is output in verbose mode.   |
|             | <code>:load-newer-no-warn</code>                                                                                                                                                                                                                                                                                 | Like <code>:load-newer</code> , but without the warning.                                                |
|             | <code>:load-fasl</code>                                                                                                                                                                                                                                                                                          | Always choose fasl files in preference to lisp files, but when verbose, warn if the lisp file is newer. |
|             | <code>:load-fasl-no-warn</code>                                                                                                                                                                                                                                                                                  | Like <code>:load-fasl</code> , but without the warning.                                                 |

|                               |                                                                                                            |
|-------------------------------|------------------------------------------------------------------------------------------------------------|
| <code>:load-lisp</code>       | Always choose lisp files in preference to fasl.                                                            |
| <code>:recompile</code>       | If the fasl file is out-of-date or there is none, compile and load the new fasl.                           |
| <code>:maybe-recompile</code> | If the fasl is out-of-date, queries whether to load it, recompile and then load it, or load the lisp file. |

Initial Value    `:load-fasl`

|             | <i>Function</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Summary     | Garbage collects a specified generation in 32-bit LispWorks.<br>This function is deprecated: use <code>gc-generation</code> instead.                                                                                                                                                                                                                                                                                                                                                                       |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Signature   | <code>mark-and-sweep gen-number =&gt; bytes</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Arguments   | <code>gen-number</code> 0 for the most recent generation, 1 for the most recent two generations, and so on up to a maximum (usually 3). Numbers outside this range signal an error.                                                                                                                                                                                                                                                                                                                        |
| Values      | <code>bytes</code> The number of bytes allocated in that generation.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Description | <code>mark-and-sweep</code> is used to garbage-collect a specified generation of storage (and all lower generations). A call to this function forces the garbage collector to scan the specified generations. This can be of use in obtaining consistent timings of programs that require memory allocation. Alternatively, performance can sometimes be improved by forcing a garbage collection, when it is known that little memory has been allocated since a previous collection, rather than waiting |

for a later, more extensive collection. For example, the function could be called outside a loop that allocates a small amount of memory.

It is specially helpful to mark and sweep generation 2 when large, long-lived data structures become garbage, because by default it is never marked and swept. The higher the generation number the more time the `mark-and-sweep` takes, but also the more space recovered.

|          |                                                                                                                                                                                                                                                                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>mark-and-sweep</code> is implemented only in 32-bit LispWorks, and is deprecated. Use <code>gc-generation</code> instead.                                                                                                                                                                                                                            |
|          | <code>mark-and-sweep</code> is not relevant to the Memory Management API in 64-bit implementations. In 64-bit implementations you can use <code>gc-generation</code> or <code>marking-gc</code> .                                                                                                                                                          |
| Examples | <code>(mark-and-sweep 0) ; collect most recent generation</code><br><code>(mark-and-sweep 3) ; collect all generations</code>                                                                                                                                                                                                                              |

| Initial value | 50                                                                                                                                                                                                                                                                                                                                                                                             |
| Description   | *max-trace-indent* is the maximum indentation that is used during output from tracing. Typically each successive invocation of tracing causes the output to be further indented, making it easier to see how the calls are nested. The value of *max-trace-indent* should be an integer.                                                                                                       |
| Example       | <pre> USER 8 &gt; (setq hcl:*max-trace-indent* 4) 4 USER 9 &gt; (defun sum (n res) (if (= n 0)                                 res                                 (+ n (sum (1- n) res)))) SUM  USER 10 &gt; (trace sum) SUM  USER 11 &gt; (sum 3 0) 0 SUM &gt; (3 0) 1 SUM &gt; (2 0) 2 SUM &gt; (1 0) 3 SUM &gt; (0 0) 3 SUM &lt; (0) 2 SUM &lt; (1) 1 SUM &lt; (3) 0 SUM &lt; (6) 6 </pre> |
| Notes         | *max-trace-indent* is an extension to Common Lisp.                                                                                                                                                                                                                                                                                                                                             |

|             | <i>key</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | An object.             |
| Description | <p>The function <b>modify-hash</b> locks the hash table <i>hash-table</i>. It then calls the function <i>function</i> with three arguments: <i>key</i>, the value currently associated with <i>key</i> in <i>hash-table</i> (if any), and a flag which is true if the key was in the table. (This last argument is needed in case the associated value is <b>nil</b>).</p> <p><b>modify-hash</b> then sets the result of the function <i>function</i> as the value for <i>key</i> in the table. <b>modify-hash</b> returns two values, the <i>new-value</i> and the <i>key</i>.</p> <p>The overall effect is like:</p> <pre>(with-hash-table-locked   <i>hash-table</i>   (multiple-value-bind (value found-p)     (gethash <i>key</i> <i>hash-table</i>)     (let ((new-value (funcall <i>function</i>                                <i>key</i> value found-p)))       (setf (gethash <i>key</i> <i>hash-table</i>) new-value)       (values new-value <i>key</i>))))</pre> <p>but <b>modify-hash</b> should be more efficient.</p> <p>It is guaranteed that no other thread can modify the value associated with <i>key</i> until <b>modify-hash</b> returns.</p> |                        |
| Notes       | <i>function</i> is called with <i>hash-table</i> locked, so it should not do anything that may require hanging the modification, or that waits for another process that tries to modify the table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                        |

| Signature   | <code>normal-gc =&gt; t</code>                                                                                                                                                                                                                                                            |
| Arguments   | None.                                                                                                                                                                                                                                                                                     |
| Values      | The function returns the single result <code>t</code> .                                                                                                                                                                                                                                   |
| Description | <p><code>normal-gc</code> resets various internal parameters that determine the frequency and extent of garbage collection to their default settings.</p> <p><code>normal-gc</code> is generally used in conjunction with <code>avoid-gc</code>, to cancel the effects of the latter.</p> |
| Notes       | <code>normal-gc</code> is useful only in 32-bit LispWorks. In 64-bit implementations it does nothing and simply returns <code>nil</code> .                                                                                                                                                |

| Initial Value | A list containing "COMMON-LISP" and other package names.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Description   | <p>LispWorks detects attempts to define external symbols in the packages on the list <code>*packages-for-warn-on-redefinition*</code>.</p> <p>LispWorks, as distributed, is configured to protect the COMMON-LISP package and other system packages.</p> <p>In particular, the effect of including "COMMON-LISP" in the list value of <code>*packages-for-warn-on-redefinition*</code> is to make all COMMON-LISP symbols be reserved words in respect of definitions and bindings. LispWorks is configured like this because ANSI Common Lisp states that the consequences of such definitions and bindings are undefined. Therefore they are best avoided.</p> <p>The action taken by LispWorks on such attempted definitions depends on the value of <code>*handle-warn-on-redefinition*</code>.</p> |

| Summary               | Parses a float from a string and returns it as float.                                                                                                                                                                                                                                                                                                             |                 |          |                   |                                              |                       |                                                                                                                                                   |  |

| Values      | <i>float</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A float |
| Description | The function <code>parse-float</code> parses a float from the substring of <i>string</i> delimited by <i>start</i> and <i>end</i> and returns it as <i>float</i> .<br><br>If the substring represents an integer or the exponent marker is E or is omitted, then <i>float</i> will be of type <code>default-format</code> , which defaults to the value of <code>*read-default-float-format*</code> . Otherwise, its type will match the exponent marker as specified by 2.3.2.2 "Syntax of a Float" in the Common Lisp standard.<br><br>If the substring does not represent an integer or a float, then an error of type <code>parse-error</code> is signalled. |         |
| Examples    | ( <code>parse-float "10"</code> ) => 10.0f0<br><br>( <code>parse-float "10" :default-format 'double-float</code> ) =><br>10.0d0<br><br>( <code>parse-float "10d0"</code> ) => 10.0d0<br><br>( <code>parse-float "10.5"</code> ) => 10.5f0<br><br>( <code>parse-float "10.5d0"</code> ) => 10.5d0                                                                                                                                                                                                                                                                                                                                                                 |         |

| <b>print-profile-list</b> |                                                                                                                                                                                    | <i>Function</i> |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary                   | Prints a report of symbols that have been profiled.                                                                                                                                |                 |
| Package                   | <code>hcl</code>                                                                                                                                                                   |                 |
| Signature                 | <code>print-profile-list &amp;key sort limit cutoff collapse =&gt; nil</code>                                                                                                      |                 |
| Arguments                 | <br><code>sort</code> <code>:call, :profile OR :top</code><br><code>limit</code> An integer.<br><code>collapse</code> A generalized boolean.<br><code>cutoff</code> A real number. |                 |

|             |                                                                                                                                                                                                      |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | <code>print-profile-list</code> returns <code>nil</code> .                                                                                                                                           |
| Description | <p>The function <code>print-profile-list</code> prints a report of symbols, after profiling using <code>profile</code>, or <code>start-profiling</code> followed by <code>stop-profiling</code>.</p> |

If the profiler was set up with `style :tree`, then a tree of calls is printed first, according to `limit`, `cutoff` and `collapse`. Then a columnar report is printed showing how often each function was called, profiled and found on the top of the stack. This report is sorted by the column indicated by the value of `sort`.

If the profiler was set up with `style :list`, then only the columnar report is printed.

`sort` can take these values:

- `:call` Sort by the number of times the function was called.
- `:profile` Sort by the number of times the function was found on the stack.
- `:top` Sort by the number of times the function was found at the top of the stack.

If `sort` is not passed then the results are printed as after the profiling run. The default is the value of the variable `*default-profiler-sort*`.

`limit` is the maximum number of lines printed in the columnar report as described for `*default-profiler-limit*`. The default is the value of the variable `*default-profiler-limit*`.

`cutoff` is the minimum percentage that the profiler will display in the output tree as described for `*default-profiler-cutoff*`. The default is the value of the variable `*default-profiler-cutoff*`.

`collapse` controls collapsing of the output tree as described for `*default-profiler-collapse*`. The default is the value of the variable `*default-profiler-collapse*`.

**Notes** You should not call `print-profile-list` while the profiler is running (see `profile` and `start-profiling`) or suspended (see `stop-profiling`).

**Example**      First set up the profiler :

```
CL-USER 1 > (set-up-profiler
 :symbols
 '(cadr car eql fixnump + 1+ caaddr caddr))

CL-USER 2 > (profile (dotimes (a 1000000 nil)
 (+ a a)
 (car '(foo))))
```

Then call `print-profile-list`:

```
CL-USER 3 > (print-profile-list :sort :call)
```

profile-stacks called 327 times

| Cumulative profile summary |     |         | called  | profile |
|----------------------------|-----|---------|---------|---------|

Top of stack not monitored 91% of the time  
NTL.

**Notes** You can suppress printing of those symbols that are currently profiled but which were not called in the profiling run by setting `system:*profiler-print-out-all*` to `nil`.

`system:*profiler-print-out-all*` is a variable defined when the profiler is loaded by `set-up-profiler`. Its initial value is `nil`.

**\*print-string\*** *Variable*

Summary      Specifies a maximum length when printing strings.

Package      `hcl`

Initial Value      `t`

Description      The variable `*print-string*` controls whether the printer uses an abbreviated form for strings when `*print-escape*` is true.

If the value of `*print-string*` is `t` then strings are printed in full as specified by ANSI Common Lisp.

If the value of `*print-string*` is `nil`, then strings are printed as unreadable objects with no specific information about the string.

If the value of `*print-string*` is an integer, then strings longer than `*print-string*` are printed as unreadable objects that include the type, length and first `*print-string*` characters.

**profile** *Macro*

Summary      Runs the specified forms, and prints a performance profile.

| Arguments   | <code>forms</code>                               | The forms making up the program being profiled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Values      | <code>final</code>                               | The result of evaluating the final form.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description |                                                  | <p>This macro starts up the LispWorks program profiler. This tool is useful for determining the time critical elements of a program.</p> <p>At a regular time interval the Lisp process is halted and the execution stack is scanned for the presence of any symbols in the list <code>*profile-symbol-list*</code>. Counters are maintained for the number of calls to each symbol, the total number of times the symbol is found on the stack, and the number of times the profiler finds the symbol on the top of the stack.</p> <p>This information is then presented as absolute numbers and as a percentage of the total number of calls to the profiler. These figures taken together give useful information about which functions the program spends most of its time executing.</p> |

**Examples**

```
(set-up-profiler
 :symbols '(* sqrt floor))
=>
20

(profile
 (let ((x 1))
 (loop for a from 1 to 500000
 do (setq x (floor (* a (sqrt x))))
 finally (return (integer-length x))))
)
=>
profile-stacks called 401 times

Call tree
Symbol seen (%)
 1: "CAPI Execution Listener 1" 401
(100)
 2: *
 2: SQRT 4 (1)
 2: FLOOR 1 (0)

Cumulative profile summary
Symbol called profile (%) top (%)
* 0 5 (1) 0 (0)
SQRT 0 4 (1) 1 (0)
FLOOR 0 1 (0) 0 (0)

On average 1.0 stacks profiled each profiler
invocation
Top of stack not monitored 100% of the time
38
```

| Summary       | The list of symbols to be profiled.                                                                                                                                                                                                                                                                                                        |
| Package       | <code>hcl</code>                                                                                                                                                                                                                                                                                                                           |
| Description   | <code>*profile-symbol-list*</code> is the list of symbols that are profiled if <code>profile</code> is called. Symbols in this list are monitored by the profiler to see if their function objects are on the stack when the profiler interrupts the Lisp process. The length of this list does not affect the speed of the profiling run. |
| Initial Value | <code>nil</code>                                                                                                                                                                                                                                                                                                                           |
| Notes         | <code>*profile-symbol-list*</code> should normally be set by one of the above functions which check that the symbol is suitable for profiling before adding them to the list.                                                                                                                                                              |
| See also      | <code>add-symbol-profiler</code><br><code>remove-symbol-profiler</code><br><code>set-up-profiler</code>                                                                                                                                                                                                                                    |

| Description | <p>The function <code>profiler-tree-from-function</code> prints a tree with root <i>function-name</i> whose children are the callees of <i>function-name</i> and their callees.</p> <p><code>profiler-tree-from-function</code> uses the data from the previous 'profile session' with style <code>:tree</code>. A profile session ends at the end of <code>profile</code> or when <code>stop-profiling</code> is called, or when the Profiler tool finishes profiling.</p> <p>In both cases the counts of profile calls is the total counts of the calls to <i>function-name</i>. Note that the percentages (the number in parentheses) are percentages from the total number of profile calls, rather than from the numbers of calls to <i>function-name</i>.</p> <p>If <i>max-depth</i> is a number it limits the depth of tree that is printed to that value. The default value of <i>max-depth</i> is <code>nil</code>, meaning no limit on the depth that is printed.</p> |

## **reset-profiler** *Function*

|           |                                                                                     |                                                                                                                                                                                                                                                                              |
|-----------|-------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | Resets the profiler so that symbols below a given threshold are no longer profiled. |                                                                                                                                                                                                                                                                              |
| Package   | <code>hcl</code>                                                                    |                                                                                                                                                                                                                                                                              |
| Signature | <code>reset-profiler &amp;key according-to =&gt; nil</code>                         |                                                                                                                                                                                                                                                                              |
| Arguments | <code>according-to</code>                                                           | One of two values — <code>:profile</code> or <code>:top</code> . This refers to which column of the profiling results <code>reset-profiler</code> uses to determine which symbols to delete from <code>*profile-symbol-list*</code> . The default is <code>:profile</code> . |
| Values    | <code>reset-profiler</code> returns <code>nil</code> .                              |                                                                                                                                                                                                                                                                              |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | This function updates the list of symbols being profiled according to the results of the previous profiling run. <code>reset-profiler</code> runs down the list of symbols being profiled and removes any symbols whose appearance in the previous profiling run falls below the value <code>*profiler-threshold*</code> . In this way the number of symbols being considered by the profiler can be reduced to just those which are important. |
| Example     | <code>(reset-profiler :according-to :top)</code>                                                                                                                                                                                                                                                                                                                                                                                                |
| Notes       | Reducing the number of symbols in <code>profile-symbol-list</code> does not actually speed up the execution of the form being profiled, but does reduce the setting up time of the profiler and the size of the list of results.                                                                                                                                                                                                                |
| See also    | <code>profile</code><br><code>*profiler-threshold*</code><br><code>print-profile-list</code><br><code>set-profiler-threshold</code>                                                                                                                                                                                                                                                                                                             |

|             | <i>Function</i>                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------|
| Summary     | Used to determine if a build script knows the real name of the image being saved.                                                |
| Package     | <code>hcl</code>                                                                                                                 |
| Signature   | <code>save-argument-real-p =&gt; realp</code>                                                                                    |
| Arguments   | None                                                                                                                             |
| Values      | <code>realp</code> A boolean.                                                                                                    |
| Description | The function <code>save-argument-real-p</code> can be used in a build script to determine if the argument passed to a subsequent |

call to `save-image` or `deliver` is the real filename of the application.

The return value `realp` is `t` in most cases. It is `nil` only when building an intermediate image for the purpose of building a universal binary, either by `save-universal-from-script` or the Application Builder (see the *LispWorks IDE User Guide*).

Operations in a build script that are related to the path of the saved image, such as building an application bundle, should be executed only when this function returns `t`. When using `save-universal-from-script`, any required application bundle should be created before calling that function (see the `save-macos-application.lisp` example below). When using the Application Builder, any required application bundle should be created in the build script only when `save-argument-real-p` returns `t`.

On architectures that do not have universal binaries, this function always returns `t`.

Example      `examples/configuration/save-macos-application.lisp`

## **save-current-session**

## *Function*

Summary      Saves the LispWorks session.

Package      `hcl`

Signature      `save-current-session pathname &rest save-image-args => result`

|             |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Description |                        | <p>The function <code>save-current-session</code> closes all windows and stops multiprocessing, saves an image at the location supplied in <i>pathname</i>, and restarts multiprocessing and the windows. For more information see “Saved sessions” on page 137.</p> <p><i>save-image-args</i> are passed to the saving function, which is <code>save-image</code> on Windows, GTK and Motif, or <code>save-image-with-bundle</code> on Cocoa.</p> <p><code>save-current-session</code> returns <code>nil</code> if the pathname supplied is unacceptable (not writable), otherwise it returns <code>t</code>. The actual operation is done asynchronously.</p> |
| Notes       |                        | <ol style="list-style-type: none"> <li>1. <code>save-current-session</code> is intended for saving the state of a windowing image. Whilst <code>save-current-session</code> can be used to save a session in a console image, this achieves nothing more than <code>save-image</code>.</li> <li>2. The released LispWorks image runs the default session. Therefore after you have used <code>save-current-session</code>, starting the supplied image (for example via the Windows start menu or Mac OS X Dock) will run itself only if the default session is "LispWorks Release".</li> </ol>                                                                 |

|           | The <code>console</code> argument is available only in LispWorks for Windows and LispWorks for Macintosh.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Arguments | <p><code>filename</code> A string. It is the name of the file that the image is saved as. This name should not be the same as the original name of the image.</p> <p><code>dll-exports</code> A list of strings, or the keyword <code>:default</code>.</p> <p><code>dll-added-files</code> A list of strings.</p> <p><code>automatic-init</code> A generalized boolean.</p> <p><code>gc</code> If non-nil, there is a garbage collection before the image is saved. The default value is <code>t</code>.</p> <p><code>type</code> Determines if some global variables are cleared before the image is saved. You can generally use the default value, which is <code>:user</code>.</p> <p><code>normal-gc</code> If this is <code>t</code> the function <code>normal-gc</code> is called before the image is saved. The default is <code>t</code>.</p> <p><code>restart-function</code> A function to be called on restart.</p> <p><code>multiprocessing</code> Controls whether multiprocessing is enabled on restart. Possible values are discussed below.</p> <p><code>console</code> On Windows <code>console</code> controls whether the new image will be a Console or GUI application and when, if ever, to make a console window in the latter case.<br/>On the Macintosh <code>console</code> controls when, if ever, to make a console window.</p> |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                    | Possible values are discussed below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>environment</i> | <i>environment</i> controls whether the LispWorks environment is started on restart. Possible values are discussed below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>remarks</i>     | <i>remarks</i> adds a comment to the save history. The value should be a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>clean-down</i>  | When <i>t</i> , calls ( <code>clean-down t</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>image-type</i>  | One of the keywords : <code>exe</code> , : <code>dll</code> and : <code>bundle</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>split</i>       | A generalized boolean. If non-nil, the Lisp heap and the executable are saved in two separate files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Values             | Returns <code>nil</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Description        | <p>The function <code>save-image</code> saves the LispWorks image to a new executable or dynamic library containing any modifications you have made to the supplied image.</p> <p>For information about the sort of changes you might want to save in a new image, see Chapter 12, “Customization of LispWorks”.</p> <p>Do not use <code>save-image</code> when the graphical IDE is running. Instead create a build script and use it with the <code>-build</code> command line argument similar to the examples below, or run LispWorks in a subprocess using the Application Builder tool.</p> <p>You cannot use <code>save-image</code> on Windows, Linux, FreeBSD, x86/x64 Solaris and Mac OS X when multiprocessing is running. It signals an error in this case.</p> <p>On Cocoa you can combine a call to <code>save-image</code> with the creation of an application bundle containing your new LispWorks image, as in the example shown below.</p> |

*dll-exports* is implemented only on Windows, Linux, x86/x64 Solaris, Macintosh and FreeBSD. It controls whether the image saved is an executable or a dynamic library (DLL). The default value is `:default` and this value means an executable is saved. The value `:com` is supported on Microsoft Windows only (see below). Otherwise *dll-exports* should be list (potentially `nil`). In this case a dynamic library is saved, and each string in *dll-exports* names a function which becomes an export of the dynamic library and should be defined as a Lisp function using `fli:define-foreign-callable`. Each exported name can be found by `GetProcAddress` (on Windows) or `dlsym` (on other platforms). The exported symbol is actually a stub which ensures that the LispWorks dynamic library has finished initializing, and then enters the Lisp code.

On Microsoft Windows the *dll-exports* list can also contain the keyword `:com`, or *dll-exports* can simply be the keyword `:com`, both of which mean that the DLL is intended to be used as a COM server. See the *LispWorks COM/Automation User Guide and Reference Manual* for details.

On Mac OS X the default behavior is to generate an object of type "Mach-O dynamically linked shared library" with file type `dylib`. See *image-type* below for information about creating another type of library on Mac OS X.

On Linux, Macintosh, x86/x64 Solaris and FreeBSD, to save a dynamic library image the computer needs to have a C compiler installed. This is typically `gcc` (which is available by installing Xcode on the Macintosh).

An image saved as a dynamic library (DLL):

- always runs multiprocessing, and
- may need to be shut down by `QuitLispWorks` or by a callback which uses `dll-quit`.

*automatic-init* specifies whether a LispWorks dynamic library should initialize inside the call to `LoadLibrary` (on Microsoft

Windows) or `dlopen` (on other platforms), or wait for further calls. Automatic initialization is useful when the dynamic library does not communicate by function calls. On Microsoft Windows it also allows `LoadLibrary` to succeed or fail according to whether the LispWorks dynamic library initializes successfully or not. Not using automatic initialization allows you to relocate the library if necessary using `InitLispWorks`, and do any other initialization that may be required. The default value of `automatic-init` is `t` on Windows, `nil` on other platforms. For more information about automatic initialization in LispWorks dynamic libraries, see Chapter 13, “LispWorks as a dynamic library”.

`dll-added-files` should be a list of filenames. It is ignored on Microsoft Windows. On other platforms if `dll-added-files` is non-nil then a dynamic library containing each named file is saved. Each file must be of a format that the default C compiler (`scm:*c-default-compiler*`) knows about and can incorporate into a shared library. Typically they will be C source files, but can also be assembler or object files. They must not contain exports that clash with names in the LispWorks shared library (see Chapter 45, “Dynamic library C functions” for the predefined exports). The added files are useful to write wrappers around calls into the LispWorks dynamic library. Such wrappers are useful for:

- Calling `InitLispWorks` when required, for example to relocate the LispWorks dynamic library to avoid memory clashes with other software, as described under “Startup relocation” on page 314.
- Calling `QuitLispWorks` when required.
- Changing calls that involve complex C structs or even C++ objects into plain calls, because accessing C structures in Lisp requires defining the structure, while in C it only needs to include the header.
- Creating ‘stub’ functions that can be called from Lisp, for example for calling a C++ method. The address of the

stub function can be passed to Lisp which can call it using a function defined by `fli:define-foreign-fun-callable`.

- Adding code that runs automatically inside the call to `dlopen`, by using `__attribute__ ((constructor))`

*image-type* defaults to `:exe` or `:dll` according to the value of `dll-exports` and therefore you do not normally need to supply *image-type*.

*image-type :bundle* is used only when saving a dynamic library. On Mac OS X it generates an object of type "Mach-O bundle" and is used for creating shared libraries that will be used by applications that cannot load dylibs (FileMaker for example). It also does not force the filename extension to be `dylib`. On other Unix-like systems *image-type* merely has the effect of not forcing the file type of the saved image, and the format of the saved image is the same as the default. On Microsoft Windows *image-type :bundle* is ignored.

**Note:** *image-type :bundle* is completely unrelated to the Mac OS X notion of an application bundle.

If *split* is `nil` (the default), then the saved image is written as a single executable file containing the Lisp heap. If *split* is `t`, then the saved Lisp heap is split into a separate file, named by adding `.lheap` to the name of the executable. When the executable runs, it reloads the Lisp heap from this file automatically.

In addition, when saving LispWorks as an application bundle on the Macintosh (for example by using `create-macos-application-bundle`), *split* can be the symbol `:resources`. This places the Lisp heap file in the `Resources` directory of the bundle, rather than in the `Contents/MacOS` directory alongside the executable, which allows the heap to be included in the signature of the bundle.

The main use of *split* is to allow third-party code signing to be applied to the executable, which is often not possible when saving an image with the Lisp heap included in a single file.

*restart-function*, if non-nil, specifies a function (with no arguments) to be called when the image is started. If *multiprocessing* is true, *restart-function* is called in a new process. *restart-function* is called after the initialization file is loaded. The default value of *restart-function* is nil.

**Note:** *restart-function* is not called if the command line argument **-no-restart-function** is present

When *multiprocessing* is nil, the executable image will start without multiprocessing enabled. When *multiprocessing* is true or the image is a DLL, the image will start with multiprocessing enabled, starting processes in the list \*initial-processes\*. When \*initial-processes\* is nil or *multiprocessing* is :with-tty-listener, a TTY listener process is started as well. The default value of *multiprocessing* is nil.

*console* is implemented only in LispWorks for Windows and LispWorks for Macintosh. The possible values for *console* are as follows:

- |                       |                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>:default</code> | Unchanged since previous save.                                                                                                                                                                                                                     |
| <code>t</code>        | On the Macintosh, the value t has the same effect as the value <code>:always</code> .<br><br>On Windows, a Console application is saved, else a Windows application is saved which creates its own console according to the other possible values. |

- |                                   |                                                                  |
|-----------------------------------|------------------------------------------------------------------|
| <code>:input, :output, :io</code> | Whenever input, output or any I/O is attempted on *terminal-io*. |
|-----------------------------------|------------------------------------------------------------------|

- |                    |                                                    |
|--------------------|----------------------------------------------------|
| <code>:init</code> | At startup, if input and output are not redirected |
|--------------------|----------------------------------------------------|

**:always** At startup, even if input and output are redirected.

The LispWorks for Windows and LispWorks for Macintosh images shipped have *console* set to **:input**.

The possible values for *environment* are as follows:

**:default** Unchanged since previous save.

**nil** Start with just the TTY listener.

**t** Start the environment automatically, no TTY listener.

**:with-tty-listener**

Start the environment automatically, but still have a TTY listener.

The LispWorks image shipped is saved with **:environment t** on all platforms except for the Motif images on Mac OS X, Solaris, HP-UX and DEC Tru64 UNIX.

You should not try to save a new image over an existing one. Always save images using a unique image name, and then, if necessary, replace the new image with the old one after the call to **save-image** has returned.

Notes

1. Do not supply **:multiprocessing nil** along with a true value of **:environment t**. Multiprocessing is needed for the GUI environment.
2. **load-image** checks that **load-all-patches** has been called. If it is called before **load-all-patches** in a session then an error is signalled.
3. In the example build scripts below, the call to **load-all-patches** is not strictly required when the script is used with the **-build** command line argument, because LispWorks 6.1 calls **load-all-patches** automatically. However, it does no harm for the build script to call **load-all-patches** too.

**Compatibility note** LispWorks 5.0 and previous versions documented `-init` as the way to run LispWorks with a build script. This method is deprecated.

Note that LispWorks quits automatically after processing a build script via `-build`, whereas with `-init` you need to call `quit` explicitly at the end of the build script.

In LispWorks 5.0 and previous versions `dll-exports` is supported only on Windows.

`dll-added-files` and `automatic-init` were new in LispWorks 5.1.

**Example** Here is an example build script. Save this to a file such as `c:/build-my-image.lisp`:

```
(load-all-patches)
(load "my-code")
(save-image "my-image")
```

Then run LispWorks with the command line argument `-build c:/build-my-image.lisp` to save the image `my-image.exe`.

This example shows a portable build script which, on Cocoa, saves your new LispWorks image in a Mac OS X application bundle. This allows your new LispWorks for Macintosh image to be launchable from the Finder or Dock and to have its own icon or other resources:

```
(load-all-patches)
(load "my-code")
#+:cocoa
(compile-file-if-needed
 (example-file
 "configuration/macos-application-bundle")
 :load t)
(save-image
 #+:cocoa
 (write-macos-application-bundle
 "/Applications/LispWorks 6.1/My LispWorks.app")
 #-:cocoa
 "my-lispworks")
```

## save-image-with-bundle

*Function*

Summary

Saves a LispWorks for Macintosh image with an application bundle, thus allowing it to work properly in the Cocoa windowing system.

Package

`hcl`

Signature

`save-image-with-bundle bundle-path &rest save-image-args  
&key bundle-arguments bundle-function &allow-other-keys`

Arguments

*bundle-path* A pathname designator.

*save-image-args* Arguments passed to `save-image`.

*bundle-arguments* Arguments passed to `bundle-function`.

*bundle-function* A function designator.

Description

The function `save-image-with-bundle` first creates the application bundle using the function `bundle-function`, and then saves the LispWorks image in the bundle.

The default value of `bundle-arguments` is `nil`.

The default value of `bundle-function` is `create-macos-application-bundle`. You can modify the created bundle by supplying `bundle-arguments`.

With the default values of *bundle-function* and *bundle-arguments*, it copies the application bundle of the running image to the bundle path with the minimal necessary modifications, and then saves an image in it. `save-image-with-bundle` checks `save-argument-real-p`, so it can be used for saving universals without further checks.

`save-image-with-bundle` operates as follows:

1. If `save-argument-real-p` returns true, it calls *bundle-function* with the *bundle-path* and *bundle-arguments*, and then uses the result as the *filename* for `save-image`. Otherwise the *filename* for `save-image` is `nil`.
2. It applies `save-image` to the path derived in the first step and the remaining arguments passed to `save-image-with-bundle` (other than *bundle-arguments* and *bundle-function*).

`save-image-with-bundle` is implemented only in LispWorks for Macintosh.

| Values      | <i>target-image</i> | A pathname designator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description |                     | <p>The function <code>save-universal-from-script</code> provides a convenient way to create a universal binary on an Intel Macintosh, using a script designed for saving a mono-architecture image.</p> <p>The <i>script-name</i> is the name of a Common Lisp build script for saving or delivering an image, as would be used to create a mono-architecture image. It should load the application and then call either <code>deliver</code> or <code>save-image</code> as appropriate.</p> <p>The function <code>save-universal-from-script</code> runs the current LispWorks image in two subprocesses, once for the PowerPC architecture (under Rosetta) and once for the native Intel architecture, passing <code>-build script-name</code> on the command line. The script is evaluated as normal, except that the filename that is passed to any call to <code>save-image</code> or <code>deliver</code> is ignored and a temporary filename is used instead. If these two subprocesses are successful, then the temporary images are combined to make a universal binary <i>target-name</i> in the same way as <code>create-universal-binary</code>.</p> <p>The command line arguments of the images run by the subprocesses will include the command line arguments that were passed to the current image. In addition, various undocumented command line arguments will be prepended, which control how <code>deliver</code> or <code>save-image</code> work in the script.</p> <p>Any output generated by the subprocesses is written to <i>output-stream</i>. If this is <code>nil</code>, then the output is discarded. If this is <code>t</code> (the default), then the output is written to the standard output.</p> |
| Notes       |                     | <p>The function <code>save-universal-from-script</code> can only be called from a LispWorks for Macintosh image that is itself a universal binary, such as the distributed image.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Example** Suppose the file `my-build-script.lisp` contains

```
(load-all-patches)
(load "my-application-defsys")
(compile-system 'my-application-system :load t)
(deliver 'my-application-function "my-application" 5)
```

Then, the following call creates a universal binary `my-application` using this script:

```
(save-universal-from-script "my-application"
 "my-build-script.lisp")
```

## set-array-single-thread-p

*Function*

**Summary** Tells the system whether an array is accessed only in a single thread context, or not.

**Package** `hcl`

**Signature** `set-array-single-thread-p array on-p`

**Arguments** `array` An array.  
`on-p` A generalized boolean.

**Description** Tells the system whether the array `array` is accessed only in a single thread context or not, depending on the value of `on-p`. Arrays that are marked for single thread access are faster for some operations, in particular `vector-push` and `vector-pop`.

| Values      | Returns <code>weakp</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                      |
| Description | <p>By default, arrays are non-weak, and they keep alive all the objects that are stored in them. A weak array may remove a pointer if the object that it points to is not pointed to from somewhere else. When a pointer is removed like this, it is replaced in <code>array</code> with <code>nil</code>.</p> <p>Pointers are replaced by <code>nil</code> after a garbage collector (GC) operation that identifies that they can be replaced. This means that if the object that is pointed to has been promoted to a higher generation, a garbage collection of the higher generation is required to remove the pointer. Note that by default the system does not automatically GC the blocking generation or higher.</p> |                                                                                                                                      |
|             | <p>The weakness state of an array can be changed many times.</p> <p>In all implementations, <code>array</code> must not be a displaced array, and the <code>array-element-type</code> of <code>array</code> must be <code>t</code>.</p> <p>In 64-bit LispWorks, an additional requirement is that <code>array</code> must be an adjustable array.</p> <p><code>set-array-weak</code> can be called at any moment.</p>                                                                                                                                                                                                                                                                                                        |                                                                                                                                      |

|          |                                                                                                                                                                    |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | An array can be made weak at creation time using the <code>:weak</code> argument to <code>make-array</code> .                                                      |

| Signature   | <code>set-default-generation num =&gt; num</code>                                                                                      |                                                                  |
| Arguments   | <code>num</code>                                                                                                                       | The number of the generation from which to do future allocation. |
| Values      | Returns <code>num</code> .                                                                                                             |                                                                  |
| Description | Set the current generation for storage allocation. By default the system allocates memory from the youngest generation (generation 0). |                                                                  |
| Notes       | <code>set-default-generation</code> is useful only in 32-bit LispWorks. In 64-bit implementations it does nothing and returns 0.       |                                                                  |
| Examples    | <pre>(set-default-generation 1) ;; allocate from an ;; older generation (set-default-generation 0) ;; return to normal</pre>           |                                                                  |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | Sets the parameters for the garbage collector in 32-bit Lisp-Works.                                                                                                                                                                                                                                                                                                                                                              |
| Package   | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Signature | <code>set-gc-parameters &amp;key maximum-buffer-size minimum-buffer-size big-object promote-min-buffer promote-max-buffer new-generation-size minimum-overflow maximum-overflow minimum-for-sweep minimum-for-promote enlarge-by-segments =&gt; &lt;no values&gt;</code>                                                                                                                                                         |
| Arguments | <p><i>maximum-buffer-size</i><br/>Maximum size of the small objects buffer.</p> <p><i>minimum-buffer-size</i><br/>Minimum size of the small objects buffer.</p> <p><i>big-object</i><br/>An object that is bigger than this value is “big”. That is, it is not allocated from the small objects buffer, but from the big-chunk area (if it is allocated in generation 0 in the normal way).</p> <p><i>promote-min-buffer</i></p> |

During promotion, a buffer is allocated in the generation being promoted into, and the objects promoted are moved into it. *promote-min-buffer* controls the minimum size of this buffer.

*promote-max-buffer*

Controls the maximum size of the promotion buffer.

*new-generation-size*

Controls the minimum enlargement of generation *gen-num*, for *gen-num* > 0. Value 0 means the generation is not expanded. Otherwise, *new-generation-size* must be a fixnum in the exclusive range (10000, 100000000) and the minimum expansion is then *new-generation-size* \* *gen-num* words. *new-generation-size* has no effect on the enlargement of generation 0.

*maximum-overflow*

Maximum size of the small-objects buffer in the big-chunk area.

*minimum-overflow*

Minimum size of the small-objects buffer in the big-chunk area.

*minimum-for-promote*

Controls the frequency of promotions. Setting *minimum-for-promote* to a high value causes the system to promote less frequently. This may improve performance for programs that allocate a lot of data for a short term and then delete it.

*minimum-for-sweep*

Controls when a mark and sweep takes place. Setting *minimum-for-sweep* to a high value causes the system to mark and sweep less often, which means it has to grow. The CPU time spent in garbage collection is mostly smaller, but the process is bigger and may cause more disk access.

#### *enlarge-by-segments*

A minimum for how much the image grows each time a segment is enlarged, as a multiple of 64K. This parameter is ignored when adding a static segment.

|             |                                                                                                                                                     |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Values      | None.                                                                                                                                               |
| Description | This function sets the parameters of the garbage collector, using the keywords described above.                                                     |
| Notes       | <code>set-gc-parameters</code> is implemented only in 32-bit Lisp-Works. It is not relevant to the Memory Management API in 64-bit implementations. |
| See also    | <code>get-gc-parameters</code>                                                                                                                      |

## **set-hash-table-weak**

*Function*

|           |                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------|
| Summary   | Sets the weakness state of a hash-table.                                                          |
| Package   | <code>hcl</code>                                                                                  |
| Signature | <code>set-hash-table-weak hash-table weak &amp;optional free-function =&gt; weakness-state</code> |
| Arguments | <code>hash-table</code> A hash-table.                                                             |

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>weak</i>          | Sets the weakness state of <i>hash-table</i> . Value may be:<br><br><b>:value or t</b> — An entry is kept if there is a pointer to the value from another object.<br><b>:key</b> — An entry is kept if there is a pointer to the key from another object.<br><b>:both</b> — An entry is kept if there are pointers to both the key and the value.<br><b>:one or :either</b> — An entry is kept if there is a pointer to either the key or the value.<br><b>nil</b> — Make the hash-table non-weak. All entries are kept.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>free-function</i> | A designator for a function of two arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Values               | Returns <i>weak</i> , unless <b>t</b> was passed, when <b>:value</b> is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description          | <p>By default, hash-tables are not weak, which means that they keep alive all the keys and the values in the table.</p> <p>A weak hash-table allows entries to be removed if there are no other pointers to them. The <i>weakness-state</i> tells the system which entries may be removed like this.</p> <p>Entries that can be removed are removed after a garbage collector (GC) operation which identifies that they can be removed. This means that if the relevant object(s) (the key or the value) have been promoted to a higher generation, a garbage collection (GC) of the higher generation is required to remove them from the table. Note that by default the system does not automatically GC the blocking generation or higher.</p> <p>The <i>weakness-state</i> of a hash-table can be changed repeatedly, at any time, at any point using any of the <i>weak</i> values listed above. It can also be set by <b>make-hash-table</b>.</p> |

*free-function* can be supplied to specify a free function as described for `make-hash-table`. It has no effect if *weak-kind* is `nil`.

| Signature   | <code>set-process-profiling <i>flag processes</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |
| Arguments   | <code>flag</code> : <code>add</code> , : <code>remove</code> or : <code>set</code> .<br><code>processes</code> One of : <code>current</code> , : <code>all</code> , a <code>mp:process</code> object, or a list of <code>mp:process</code> objects which may also contain : <code>current</code> .                                                                                                                                                                                                                                                                                                                                                             |  |
| Description | <p>The function <code>set-process-profiling</code> modifies the set of processes for which profiling information is (or will be) collected.</p> <p>If <code>set-process-profiling</code> is called while profiling (that is after a call to <code>start-profiling</code> and before the next call to <code>stop-profiling</code> with <code>print</code> non-nil) the system immediately starts collecting profile information for the new set of processes.</p> <p>When <code>start-profiling</code> is called without passing <code>processes</code>, it sets the processes to profile according to the last call to <code>set-process-profiling</code>.</p> |  |

*flag* determines how the set of processes to profile is modified:

- |                      |                                               |
|----------------------|-----------------------------------------------|
| <code>:add</code>    | The given processes are added to the set.     |
| <code>:remove</code> | The given processes are removed from the set. |
| <code>:set</code>    | The given processes are used as the set.      |
- processes* controls which processes are added to the set, removed from the set or are contained in the set, as follows:
- |                       |                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>:current</code> | Means the current process. When <code>start-profiling</code> is called it interprets <code>:current</code> to mean the current process at the time it is called. If <code>set-process-profiling</code> is called while profiling, <code>:current</code> is interpreted as the current process when <code>set-process-profiling</code> is called. |
| <code>:all</code>     | Means all processes, including those which are created after profiling started.                                                                                                                                                                                                                                                                  |

#### A `mp:process` object

Means that process.

A list Means the processes in that list. The list can contain the symbol `:current`, which is interpreted as described above.

`set-process-profiling` can be called whether or not the profiler is collecting information. See `start-profiling` and `stop-profiling`.

Examples Add *process1* to the set:

```
(set-process-profiling :add process1)
```

Turn off profiling for the current process:

```
(set-process-profiling :remove :current)
```

Turn off all profiling:

```
(set-process-profiling :remove :all)
```

Set all processes for later profiling:

```
(set-process-profiling :set :all)
```

## set-profiler-threshold *Function*

Summary      Sets the percentage threshold for symbols to be profiled in a subsequent run.

Package      **hcl**

Signature      **set-profiler-threshold value => value**

Arguments      *value* must be a fixnum between 0 and 100.

Values      **set-profiler-threshold** returns *value*.

Description      This function sets the value of **\*profiler-threshold\*** below which symbols are not profiled in a repeated profiling run. After a profiling run, all the symbols being profiled have a percentage value for the amount of time they were on the top of the stack. If **\*profiler-threshold\*** is set to 40 then by running **reset-profiler** with argument **:top** all symbols which are found on the top of the stack less than forty percent of the time are removed from the list of those symbols considered for profiling.

Example      **(set-profiler-threshold 40)**

**set-system-message-log** *Function*

Summary      Manipulates the system message log.

Package      **hcl**

Signature      **set-system-message-log &key stream collect get callback => result**

Arguments      **stream**      An output stream designator, or :no-change.

**collect**     A boolean, or :no-change.

**get**        t or :keep.

**callback**   A function designator, or :no-change.

Values          **result**     A list of strings, or nil.

Description      The function **set-system-message-log** manipulates the system message log. This log is used by the system to produce messages that indicate that something is not as expected, but is not an error. For example, putting a bad Break-Gesture in a GTK resource file.

If **stream** is t or a stream, the system message log stream is set, with t meaning \*standard-output\*. This stream is used when writing messages.

When **collect** is true but not :no-change, messages are collected in an internal list, which can be retrieved by using **get**.

*callback* can be a designator for a function of one argument, a string. This function is called when a message is generated. The callback must not try to perform GUI operations.

The default value of each of *stream*, *collect* and *callback* is :**no-change**, which does not change the current setting.

When *get* is supplied **set-system-message-log** returns a list of the messages that has been collected. Each message is a single string. If *get* is **t**, the internal list is reset to **nil**. If *get* is :**keep**, the internal list is not reset, so the next call with *get* will get them again.

**set-system-message-log** returns **nil** if *get* is not supplied.

**set-system-message-log** returns the list of collected messages if *get* is supplied.

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes | <p><i>stream</i>, <i>callback</i> and <i>collect</i> are mutually independent. It is possible to set the system to any combination of these.</p> <p>The order of operation when a message is generated is first to print, then call the callback, and then collect.</p> <p>When collecting messages it can accumulate, so it is important to periodically get the message to ensure it does not bloat the memory.</p> <p>Using <i>collect t</i> when it is already collecting has no effect, in particular it does not affect the list of collected messages.</p> |

|             | <i>show-unknown-frames</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | A generalized boolean.                                                   |
| Values      | The time interval is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                          |
| Description | <p><code>set-up-profiler</code> is used to declare the values of the parameters of the profiling function. Three values are required, as follows.</p> <p><i>symbols</i>, if non-nil, specifies which symbols are to be monitored by the profiler. Each symbol in <i>symbols</i> is checked to see if it is suitable for profiling and if so it is added to the list <code>*profile-symbol-list*</code>.</p> <p>If <i>symbols</i> is not passed then <i>packages</i> specifies which symbols are to be monitored. If <i>packages</i> is <code>:all</code>, then all packages are monitored. All the symbols in the packages are checked as above. If a <i>symbols</i> argument is present then <i>packages</i> is ignored.</p> <p><i>kind</i> specifies the way that the time between samples is measured on Unix-like platforms:</p> <ul style="list-style-type: none"> <li><code>:profile</code>      Process time only.</li> </ul> |                                                                          |

**:virtual**      Process time and system time for the process.

**:real**        Real time.

The default value of *kind* is **:profile**.

**Note:** *kind* is ignored on Microsoft Windows platforms.

*interval* specifies the interval in microseconds between profile samples. The minimum value of *interval* is 10000, that is 10 ms. The default value of *interval* is 10000.

*limit*, when non-nil, sets **\*default-profiler-limit\***. This limits the maximum number of lines printed in the profile output (not including the tree). The default value is 100.

*cutoff*, when non-nil, sets **\*default-profiler-cutoff\***. This is the default minimum percentage that the profiler will display in the output tree. Functions below this percentage will not be displayed. The default is **nil**, that is there is no cutoff.

*collapse* specifies whether functions with only one callee in the profile tree should be collapsed, that is, only the child is printed. When passed, sets **\*default-profiler-collapse\***. The default value of *collapse* is **nil**.

*style* controls the format of output. If *style* is not passed or passed as **nil**, the format does not change. If *style* is passed, it can take these values:

**:list**        The profiler will show the functions seen on the stack.

**:tree**       The profiler will generate a tree of calls seen in the profiler, as well as the output shown by **:list**.

The default value of *style* is **:tree**.

*gc* specifies whether to profile functions inside the memory management code (more accurately, functions that are called

on the GC stack) in addition to any other profiling. The default value of `gc` is `nil`.

`show-unknown-frames` controls whether the profile tree shows nodes where the name of the function is unknown. The default value of `show-unknown-frames` is `nil`.

`call-counter` specifies whether to add extra code to count calls. The counting is done dynamically. If `call-counter` is `nil`, call counters are not added, and the call counter of all functions is displayed as 0. The default value of `call-counter` is `nil` on Intel-based platforms and `t` on other platforms. This is because the counting significantly affects the performance of applications using Symmetric Multiprocessing (SMP).

#### Notes

1. Call counting can affect performance significantly on some platforms. To get accurate timing (in scales of a few percentage points), pass `call-counter nil`. However, in most cases the profiler is used to find bottlenecks where the slowdown is hundreds of percentage points and so the effect of call counting is less significant.
2. `call-counter` is effective only on x86 platforms or in 64-bit LispWorks. On non-x86 platforms 32-bit LispWorks does call counting for a given function if the compiler optimize quality `debug` is greater than 0 at compile-time, and `call-counter` has no effect.

#### Example

```
(set-up-profiler :symbols '(car cdr)
 :interval 50000)
```

On Unix/Linux/Mac OS X:

```
(set-up-profiler :symbols '(car cdr)
 :kind :profile :interval 50000)
```

| Summary     | Lists special variables set by a definition.                                                                                          |                               |
| Package     | <b>hcl</b>                                                                                                                            |                               |
| Signature   | <b>sets-who</b> <i>function</i> => <i>result</i>                                                                                      |                               |
| Arguments   | <i>function</i>                                                                                                                       | A symbol or a function dspec. |
| Values      | <i>result</i>                                                                                                                         | A list.                       |
| Description | The function <b>sets-who</b> returns a list of the special variables set by the definition named by <i>function</i> .                 |                               |
| Notes       | The cross-referencing information used by <b>sets-who</b> is generated when code is compiled with source-level debugging switched on. |                               |

## **source-debugging-on-p** *Function*

|           |                                                          |  |
|-----------|----------------------------------------------------------|--|
| Summary   | Tests if source level debugging is on for compiled code. |  |
| Package   | <b>hcl</b>                                               |  |
| Signature | <b>source-debugging-on-p</b> => <i>bool</i>              |  |
| Arguments | None.                                                    |  |

|             |             |                                                                                                                |
|-------------|-------------|----------------------------------------------------------------------------------------------------------------|
| Values      | <i>bool</i> | If <code>t</code> , source level debugging is on.                                                              |
| Description |             | Returns <code>t</code> if source level debugging is on for compiled code; otherwise returns <code>nil</code> . |
| See also    |             | <code>toggle-source-debugging</code>                                                                           |

## **start-profiling** *Function*

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Summary     | Starts collecting profiling information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                            |

| Description | <p>The function <code>start-profiling</code> starts collecting profiling information. If <code>initialize</code> is non-<code>nil</code> any profiling information collected so far is discarded. The default value of <code>initialize</code> is <code>t</code>. If <code>processes</code> is supplied, the set of processes that will be profiled is set as if by calling:</p> <pre>(set-process-profiling :set :processes processes)</pre> <p>Otherwise, the set of processes remains unchanged, so is controlled by any previous calls to <code>set-process-profiling</code>. <code>profile-waiting</code> is used only in SMP LispWorks. When <code>profile-waiting</code> is true, processes that are marked for profiling are</p> |                                                                                                                            |

profiled even if they are in a wait state. In non-SMP Lisp-Works, only processes that are active are profiled.

*ignore-in-foreign* controls whether to ignore processes that are inside foreign calls. The default value of *ignore-in-foreign* is `nil`.

`start-profiling` can be repeatedly called without intervening calls to `stop-profiling`, for example to change the setting of *profile-waiting* or the profiled processes.

`start-profiling` cannot be used while `profile` is used or while the Profiler tool is profiling (on any thread). Between the call to `start-profiling` and the next call to `stop-profiling` with `print t` (or omitted), `profile` and the Profiler tool cannot be used.

Various parameters which are set by `set-up-profiler` control the behavior of the profiler. See the documentation for `set-up-profiler`.

## Examples

The following sequence of calls to `start-profiling` and `stop-profiling` can be used to profile only interesting work and print the results:

Start profiling the current process:

```
(start-profiling :processes :current)
(do-interesting-work)
```

Temporarily suspend profiling:

```
(stop-profiling :print nil)
(do-uninteresting-work)
```

Resume profiling:

```
(start-profiling :initialize nil)
(do-more-interesting-work)
(stop-profiling)
```

| <i>stream</i>         | An output stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |              |                        |               |                   |
| Description           | <p>The function <b>stop-profiling</b> stops collecting profiling information, and optionally prints the results.</p> <p>If <i>print</i> is non-nil, the information collected so far is printed and the next call to <b>start-profiling</b> must pass <i>initialize t</i> or omit the <i>initialize</i> argument. If <i>print</i> is nil, then the profiler is put into a suspended state where no profiling information is collected, but can be restarted by calling</p> <pre>(start-profiling :initialize nil)</pre> <p>The default value of <i>print</i> is t.</p> <p><i>stream</i> specifies the stream for output when <i>print</i> is non-nil. It is ignored when <i>print</i> is nil. The default value of <i>stream</i> is the value of *trace-output*.</p> |              |                        |               |                   |
| Notes                 | Parameters set by <b>set-up-profiler</b> control the format of the output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |              |                        |               |                   |

| Description     | <p>Applies <i>function</i> to all the live objects in the image. Normally it is not useful to sweep objects in generation 0 because they are ephemeral, so by default <code>sweep-all-objects</code> does not sweep generation 0. This can be changed by passing a non-nil value as <i>gen-0</i>.</p> <p><i>function</i> should take one argument, the object. It can allocate, but if it allocates heavily the sweeping becomes unreliable. Small amounts of allocation will normally happen only in generation 0, and so will not affect sweeping of other generations.</p> <p>To call <code>sweep-all-objects</code> reliably, do it inside <code>with-other-threads-disabled</code>.</p> |                 |                                         |              |                                                       |
| Notes           | In 64-bit LispWorks there is a more specific alternative: function <code>sweep-gen-num-objects</code> can be used to call a function on all live objects in a particular generation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                 |                                         |              |                                                       |

The default is <code>t</code> . |
| Values      | <code><i>bool</i></code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | The current state of source level debugging:<br><code>t</code> if source level debugging is on.                                |
| Description | <p><code>toggle-source-debugging</code> sets certain compiler parameters, and also turns leaf case optimizations on (when called with <code>nil</code>) or off (when called with <code>t</code>). For all these parameters, the value <code>nil</code> reduces compilation speed.</p> <p><code>toggle-source-debugging</code> is called in the configuration file <code>a-dot-lispworks.lisp</code>, and the initial state of LispWorks such that source level debugging is on.</p> <p>The parameters relate to information required for source level debugging, cross-referencing and finding all changed definitions.</p> |                                                                                                                                |
|             | The parameters (all in the <code>compiler</code> package) are:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                |
|             | <b>*produce-xref-info*</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                |
|             | When true, the compiler produces information for the Cross Referencer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                |
|             | <b>*load-xref-info*</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                |
|             | When true, the cross-referencing information produced by the compiler is loaded when the corresponding file is loaded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                |

**\*notice-changed-definitions\***

When true, the Cross Referencer notices when a function is redefined, including an interpreted redefinition..

**\*source-level-debugging\***

When true, the compiler generates information used by the debugger.

`toggle-source-debugging` modifies the status of the variables, and then returns the new value. To check whether all the variables are set to true, without modifying them, use `source-debugging-on-p`.

Cross-referencing information is used by the functions `who-calls`, `who-binds`, `who-references`, `who-sets`, and friends.

**Compatibility note** In LispWorks 4.2 and earlier, `toggle-source-debugging` controlled source file recording information. In LispWorks 4.3 and later, this is controlled independently by `*record-source-files*`.

## **total-allocation** *Function*

**Summary** Calculate memory consumed since the image was started.

**Package** `hcl`

**Signature** `total-allocation`

**Arguments** None.

**Values** Returns the amount allocated

|             |                                                                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | This function calculates the total amount of memory consumed since the current image was created. Use at the start and end of a piece of code, to see how much it allocates. |

| Summary       | The list of arguments given to the function being traced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Package       | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Initial Value | <code>nil</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description   | Upon entering a function that is being traced, <code>*traced-arglist*</code> is bound to the list of arguments given to the function. <code>*traced-arglist*</code> is then printed after the function name in the output from tracing. It is accessible in the <code>:before</code> and <code>:after</code> forms to <code>trace</code> . However care should be used when manipulating this variable, since it is the value of <code>*traced-arglist*</code> itself that is used when calling the traced function. Thus if this value is altered by the <code>:before</code> forms then the function receives the altered argument list. |
| Example       | <pre>USER 14 &gt; (trace (+ :before                       ((setq *traced-arglist*                            (mapcar #'1+                                    *traced-arglist*))))) + USER 15 &gt; (+ 1 2 3) 0 + &gt; (1 2 3) (2 3 4) 0 + &lt; (9) 9</pre>                                                                                                                                                                                                                                                                                                                                                                                  |
| Notes         | <code>*traced-arglist*</code> is an extension to Common Lisp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## \*traced-results\*

## *Variable*

**Summary** The list of results from the function being traced.

## Package hcl

Initial Value      nil

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | Upon leaving a function that is being traced, <b>*traced-results*</b> is bound to the list of results from the function. <b>*traced-results*</b> is then printed after the function name in the output from tracing. It is accessible in the <code>:after</code> forms to <code>trace</code> . However care should be used when manipulating this variable, since it is the value of <b>*traced-results*</b> itself that is used when returning from the traced function. Thus if this value is altered by the <code>:after</code> forms then the caller of the traced function receives the altered results. |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
Example USER 5 > (trace (ceiling
 :after
 ((setq *traced-results*
 (mapcar #'l- *traced-results*)))))

CEILING
USER 6 > (multiple-value-call #'+ (ceiling 4 3))

0 CEILING > (4 3)
0 CEILING < (2 -2)
 (1 -3)
-2
```

Notes \*traced-results\* is an extension to Common Lisp.

| <b>*trace-indent-width*</b> | <i>Variable</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Summary                     | The amount of extra indentation in the trace output for each level of nesting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Package                     | hcl                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Initial Value               | 2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description                 | <b>*trace-indent-width*</b> is the extra amount by which the traced output for function calls is indented upon entering a deeper level of nesting (that is, a traced call from a function that is itself traced). If it is 0 then no indentation occurs.                                                                                                                                                                                                                                                                                                                                                               |
| Example                     | <pre>CL-USER 1 &gt; (setq *trace-indent-width* 4                       *max-trace-indent* 50) 50  CL-USER 2 &gt; (defun quad (a b c) (- (* b b) (* 4 a c))) QUAD  CL-USER 3 &gt; (trace quad *) (QUAD *)  CL-USER 4 &gt; (quad 4 3 14) 0 QUAD &gt; ...     &gt;&gt; A : 4     &gt;&gt; B : 3     &gt;&gt; C : 14         1 * &gt; ...             &gt;&gt; SYSTEM::ARGS : (3 3)         1 * &lt; ...             &lt;&lt; VALUE-0 : 9         1 * &gt; ...             &gt;&gt; SYSTEM::ARGS : (4 4 14)         1 * &lt; ...             &lt;&lt; VALUE-0 : 224 0 QUAD &lt; ...     &lt;&lt; VALUE-0 : -215 -215</pre> |
| Notes                       | <b>*trace-indent-width*</b> is an extension to Common Lisp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

\*trace-level\*

## Variable

**Summary** The current depth of tracing.

## Package hcl

Initial Value 0

|             |                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | * <b>trace-level</b> * is a special variable whose value is the current depth of tracing. The current value of * <b>trace-level</b> * is printed before the function name during the output from tracing. |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
Example USER 8 > (defun fac (n) (if (<= n 1)
 1
 (* n (fac (1- n)))))

 FAC
USER 9 > (trace fac)

 FAC
USER 10 > (fac 3)

0 FAC > (3)
1 FAC > (2)
2 FAC > (1)
2 FAC < (1)
1 FAC < (2)
0 FAC < (6)
6
```

Notes \*trace-level\* is an extension to Common Lisp.

| Initial Value               | <code>nil</code>                                             |                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description                 |                                                              | <code>*trace-print-circle*</code> controls how circular structures are printed during output from tracing. It allows the printing of circular structures by the tracer to be controlled independently of the usual printing mechanism, which is governed by <code>*print-circle*</code> . <code>*print-circle*</code> is bound to the value of <code>*trace-print-circle*</code> while printing tracing information. |
| Example                     |                                                              | <pre> USER 19 &gt; (setq *trace-print-circle* t)  T USER 20 &gt; (defun circ (l)               (rplacd (last l) 1)               1)  CIRC USER 21 &gt; (trace second)  SECOND USER 22 &gt; (second (circ '(1 2 3 4))) 0 SECOND &gt; (#1=(1 2 3 4 . #1#)) 0 SECOND &lt; (2) 2 </pre>                                                                                                                                  |
| Notes                       |                                                              | <code>*trace-print-circle*</code> is an extension to Common Lisp.                                                                                                                                                                                                                                                                                                                                                    |

| Initial value | <code>5</code>                                                 |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p><code>*trace-print-level*</code> controls the depth to which nested objects are printed during output from tracing. If its value is a positive integer then components at or above that level are suppressed. By definition an object to be printed is considered to be at level 0, its components are at level 1, their sub-components are at level 2, and so on.</p> <p><code>*print-level*</code> is bound to the value of <code>*trace-print-level*</code> while printing tracing information. If <code>*trace-print-level*</code> is <code>nil</code> then objects are printed without regard to depth.</p> |
| Examples    | <pre>USER 8 &gt; (trace append)  APPEND USER 9 &gt; (dotimes (i 10) (setq li (if (zerop i)                                              nil                                              (list i li)))))  NIL USER 10 &gt; (append li '(a b)) 0 APPEND &gt; ((9 (8 (7 (6 #)))) (A B)) 0 APPEND &lt; ((9 (8 (7 (6 #))) A B)) (9 (8 (7 (6 (5 (4 (3 (2 (1 NIL))))))) A B)</pre>                                                                                                                                                                                                                                        |
| Notes       | <p><code>*trace-print-level*</code> is an extension to Common Lisp.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Summary                     | Controls the amount of whitespace in trace output.                                                                                                      |                 |
| Package                     | <code>hcl</code>                                                                                                                                        |                 |
| Initial Value               | <code>nil</code>                                                                                                                                        |                 |
| Description                 | <p><code>*trace-print-pretty*</code> controls the amount of whitespace printed during output from tracing. If it is not <code>nil</code> then extra</p> |                 |

whitespace is inserted to make the output more comprehensible. **\*print-pretty\*** is bound to the value of **\*trace-print-pretty\*** while printing tracing information.

## Examples

```

USER 6 > (trace macroexpand-1)

MACROEXPAND-1
USER 7 > (setq *trace-print-pretty* t
 print-pretty nil)

NIL
USER 8 > (defmacro sum (n)
 ' (do ((i 0 (1+ i))
 (res 0 (+ i res)))
 ((= i ,n) res)))

SUM
USER 9 > (macroexpand-1 '(sum 3))

0 MACROEXPAND-1 > ((SUM 3))
0 MACROEXPAND-1 < ((DO ((I 0 (1+ I))
 (RES 0 (+ I RES)))
 ((= I 3)
 RES))
 T)
 (DO ((I 0 (1+ I)) (RES 0 (+ I RES))) ((= I 3) RES))
 T

```

## Notes

**\*trace-print-pretty\*** is an extension to Common Lisp.

## try-compact-in-generation *Function*

|           |                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Summary   | Compacts the most fragmented segment(s) in a generation in 32-bit LispWorks.                                                                                                                                                                                                                                                                                                                 |
| Package   | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                             |
| Signature | <code>try-compact-in-generation <i>generation-number time-threshold</i>&amp;optional <i>fraction-threshold</i> =&gt; <i>result</i></code>                                                                                                                                                                                                                                                    |
| Arguments | <p><i>generation-number</i><br/>0 for the most recent generation, 1 for the most recent two generations, and so on up to a maximum (usually 3). Numbers outside this range signal an error.</p> <p><i>time-threshold</i> A real number.</p> <p><i>fraction-threshold</i><br/>A real number between 0 and 1, defining the minimum fragmentation to actually compact. The default is 0.25.</p> |
| Values    | <i>result</i><br>A boolean.                                                                                                                                                                                                                                                                                                                                                                  |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p><code>try-compact-in-generation</code> finds the most fragmented segment in the generation specified. If <i>time-threshold</i> is positive, it compacts this segment, and repeats this operation until <i>time-threshold</i> seconds have elapsed. At this point <code>try-compact-in-generation</code> returns, with value <code>t</code> if at least one segment was compacted and value <code>nil</code> otherwise. Because the operation cannot be stopped in the middle, the actual time taken will always be larger than <i>time-threshold</i>.</p> <p>If <i>fraction-threshold</i> is 1, <code>try-compact-in-generation</code> does nothing. If <i>fraction-threshold</i> is 0, <code>try-compact-in-generation</code> will compact all uncompacted segments (unless it runs out of time). With the default (0.25) <code>try-compact-in-generation</code> compacts only moderately fragmented segments.</p> <p>If <i>time-threshold</i> is negative, then <code>try-compact-in-generation</code> does not actually compact any segments. <i>result</i> is a boolean indicating whether <code>try-compact-in-generation</code> would actually try to compact a segment if it were to be called with a positive <i>time-threshold</i> and the other arguments unchanged.</p> <p>This function is typically used after a call to <code>check-fragmentation</code>. For more information, see “Controlling Fragmentation” on page 115.</p> |
| Notes       | <p><code>try-compact-in-generation</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations, where <code>marking-gc</code> with the <i>what-to-copy</i> argument offers similar functionality (although <code>set-blocking-gen-num</code> is intended to solve the problem of fragmentation automatically).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Summary     | Moves objects out of the most fragmented segment(s) in a generation, leaving them empty in 32-bit LispWorks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Package     | <code>hcl</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Signature   | <code>try-move-in-generation generation-number time-threshold &amp;optional fraction-threshold =&gt; result</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Arguments   | <p><i>generation-number</i><br/>0 for the most recent generation, 1 for the most recent two generations, and so on up to a maximum (usually 3). Numbers outside this range signal an error.</p> <p><i>time-threshold</i> A real number.</p> <p><i>fraction-threshold</i><br/>A real number between 0 and 1, defining the minimum fragmentation to actually move. The default is 0.25.</p>                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Values      | <i>result</i> A boolean.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description | <p><code>try-move-in-generation</code> finds the most fragmented segment in the generation specified. If <i>time-threshold</i> is positive, it moves objects out of this segment, leaving it empty, and repeats this operation until <i>time-threshold</i> seconds have elapsed. At this point <code>try-move-in-generation</code> returns, with value <code>t</code> if at least one segment was moved and value <code>nil</code> otherwise. Because the operation cannot be stopped in the middle, the actual time taken will always be larger than <i>time-threshold</i>.</p> <p>If <i>fraction-threshold</i> is 1, <code>try-move-in-generation</code> does nothing. If <i>fraction-threshold</i> is 0, <code>try-move-in-generation</code> will move all uncompacted segments (unless it runs out of</p> |

time). With the default (0.25) `try-move-in-generation` moves only moderately fragmented segments.

If `time-threshold` is negative, then `try-move-in-generation` does not actually move any segments. `result` is a boolean indicating whether `try-move-in-generation` would actually try to move a segment if it were to be called with a positive `time-threshold` and the other arguments unchanged.

This function is typically used after a call to `check-fragmentation`. For more information, see “Controlling Fragmentation” on page 115.

|          |                                                                                                                                                                                                                                                                                                                                                                              |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Notes    | <code>try-move-in-generation</code> is implemented only in 32-bit LispWorks. It is not relevant to the Memory Management API in 64-bit implementations, where <code>marking-gc</code> with the <code>what-to-copy</code> argument offers similar functionality (although <code>set-blocking-gen-num</code> is intended to solve the problem of fragmentation automatically). |

Description      The macro `unwind-protect-blocking-interrupts` executes *protected-form* with interrupts blocked. On exit, whether local or not, the *cleanups* are executed with interrupts blocked.

In compiled code, the macro is equivalent to

```
(mp:with-interrupts-blocked
 (unwind-protect
 protected-form
 (mp:current-process-block-interrupts)
 cleanup1 cleanup2 ...)))
```

However, in interpreted code the macro is expanded to ensure that the call to `(mp:current-process-block-interrupts)` actually happens. If the above form is interpreted and *protected-form* uses `current-process-unblock-interrupts`, the evaluator may throw (if the process is killed, for example) before calling `current-process-unblock-interrupts`.

- Notes
1. Both the protected form and the cleanups can block and unblock interrupts using `current-process-block-interrupts` and `current-process-unblock-interrupts`. Typically the protected form would set up something and then unblock the interrupts. The cleanups may unblock interrupts if some of the cleanups are essential and others are not.
  2. Blocking interrupts causes the process to not respond to interrupts, including killing. You should make sure that forms which are executed with interrupts blocked do not hang.

| Values      | <i>results</i> The values of <i>protected-form</i> .                                                                                                                                                                                                                                                                                                |
| Description | The macro <code>unwind-protect-blocking-interrupts-in-cleanups</code> executes <i>protected-form</i> . On exit, whether local or not, the <i>cleanups</i> are executed with interrupts blocked.                                                                                                                                                     |
|             | In compiled code, the macro is equivalent to                                                                                                                                                                                                                                                                                                        |
|             | <pre>(unwind-protect   <i>protected-form</i>   (mp:with-interrupts-blocked <i>cleanup1 cleanup2 ...</i>)</pre>                                                                                                                                                                                                                                      |
|             | However, in interpreted code the macro is expanded to ensure that the body of <code>mp:with-interrupts-blocked</code> actually happens. If the form above is interpreted the evaluator may throw (if the process is killed, for example) before completing macroexpansion of <code>mp:with-interrupts-blocked</code> and doing the actual blocking. |
| Notes       | <ol style="list-style-type: none"> <li>1. <i>cleanups</i> can block and unblock interrupts using <code>current-process-block-interrupts</code> and <code>current-process-unblock-interrupts</code>. This may be useful if some of the cleanups are essential and others are not.</li> </ol>                                                         |

- Blocking interrupts causes the process to not respond to interrupts, including killing. You should make sure that forms which are executed with interrupts blocked do not hang.

## **variable-information** *Function*

Summary      Returns information about the variable bindings of a symbol in an environment.

Package      `hcl`

Signature      `variable-information variable &optional env => kind,  
                   localp, decls`

Arguments      `variable`      A symbol

`env`      An environment or `nil`

Values      `kind`      `nil` or one of the keywords `:special`,  
                   `:lexical`, `:symbol-macro` and `:constant`.

`localp`      A boolean

`decls`      An a-list

Description      The function `variable-information` returns information about how the variable `symbol` is bound in the environment `env`.

The value of `kind` will be as follows:

`nil`      There is no information about `variable` in `env`

`:special`      `variable` has a special binding in `env`

**:lexical**      *variable* has a lexical binding in *env*  
**:symbol-macro** *variable* has a symbol-macro binding in *env*  
**:constant**      *variable* has a constant binding in *env*

*localp* will be true if *variable* is bound by a form that has lexical scope (for example `let`, `lambda`) or false if *variable* has global scope (for example `defvar`).

*decls* is an a-list of declarations that refer to *variable*. The `cdr` of each pair is specified according to the `car` of the pair as follows:

**dynamic-extent**

The `cdr` is non-nil if *variable* is declared **dynamic-extent** in *env*.

**ignore**      The `cdr` is non-nil if *variable* is declared **ignore** in *env*.

**type**      The `cdr` is the type specifier that is declared for *variable* in *env* if any.

**Notes**      **variable-information** is part of the environment access API which is based on that specified in *Common Lisp: the Language* (2nd Edition).

| Values      | <i>results</i>                                                                                                                                                                                                                                                                                                                                                                                                                                       | The results of evaluating <i>body</i> . |
| Description | <p>The macro <code>with-hash-table-locked</code> evaluates <i>body</i> with the hash table <i>hash-table</i> locked against modification by other threads. The current thread can modify <i>hash-table</i>.</p> <p><code>with-hash-table-locked</code> is useful not only for multiple accesses to the same table, but also when an access to the table must be consistent with some other operation, avoiding the need to make a separate lock,</p> |                                         |

| Arguments          | <i>body</i>                                                                                                                                                                                                                                                      | The forms for which you want the garbage collector to behave differently from normal. |
| Values             | <i>result</i>                                                                                                                                                                                                                                                    | The result of executing <i>body</i> .                                                 |
| Description        | The macro <b>with-heavy-allocation</b> is for use with code that allocates a lot of space but is not interactive. It ensures that garbage collection (GC) is carried out less frequently while these forms are being executed. However, each GC may take longer. |                                                                                       |
| Compatibility note | In LispWorks 5.0 <b>with-heavy-allocation</b> is implemented only in 32-bit LispWorks. In version 5.1 and later it is implemented in 64-bit LispWorks as well.                                                                                                   |                                                                                       |
